

POLYPEPTIDES INVOLVED IN THE BIOSYNTHESIS OF  
STREPTOGRAMINS, NUCLEOTIDE SEQUENCES CODING FOR THESE  
POLYPEPTIDES AND THEIR USE

The present invention relates to novel  
5 polypeptides involved in the biosynthesis of  
streptogramins, and also comprises the isolation and  
identification of genes for the biosynthesis of the A  
and B components of streptogramins, the expression of  
these genes with the object of increasing the levels of  
10 production and their use for the construction of  
blocked mutants capable of leading to the synthesis of  
novel antibiotics or to derived forms of  
streptogramins.

Streptogramins form a homogeneous group of  
15 antibiotics, consisting of a combination of two types  
of molecules which are chemically different; on the one  
hand polyunsaturated macrolactones (A-group components,  
two examples of structures of which are presented in  
Figure 1), and on the other hand depsipeptides (B-group  
20 components, three examples of the structure of which  
are presented in Figure 2). This group comprises many  
antibiotics (see Table 1 and Figure 3), which are known  
by different names in accordance with their origin,  
including pristinamycins, mikamycins and virginiamycins.  
25 (for a review, see Cocito 1979, 1983).

The A and B components have a synergistic  
antibacterial activity which can reach 100 times that  
of the separate components and which, in contrast to

that of each component, is bactericidal (Cocito 1979). This activity is more especially effective against Gram-positive bacteria such as staphylococci and streptococci (Cocito 1979, Videau 1982). The A and B  
5 components inhibit protein synthesis by binding to the 50S subunit of the ribosome (Cocito 1979; for a review, see Di Giambattista et al. 1989).

Streptogramins are chiefly produced by actinomycetes, including many streptomycetes, presented  
10 in Table 1. In addition, streptogramins are also synthesized by eukaryotes such as Micromonospora which synthesizes vernamycins. Actinomycetes constitute a very important group of microorganisms on account of the large amount of secondary metabolites they produce,  
15 including many antibiotics (beta-lactams, tetracyclines, macrolides, aminoglycosides, polyacetates and the like), herbicides, anticancer agents, antifungal agents, immunomodulators and enzyme inhibitors. Many biosynthesis pathways relating to  
20 antibiotics belonging to miscellaneous classes as well as other secondary metabolites such as pigments (for a review, Chater 1990) have already been studied at the present time in actinomycetes. An important aspect of this group of bacteria is that the genes involved in  
25 the same biosynthesis pathway, structural genes and also resistance gene(s) and regulatory gene(s), are grouped together physically on the chromosome, constituting clusters which can reach more than 100 kb

(Hopwood et al. 1986a, Hopwood et al. 1986b, Hallam et al. 1988, Anzai et al. 1987, Ohnuki et al. 1985). To date, no example has been found to contradict this observation. Such a structural organization is of great  
5 interest in the development of strategies for cloning biosynthesis genes. In effect, it is possible, starting from a single gene previously cloned by various techniques, a biosynthesis, resistance or regulatory gene, to walk along the chromosome and thus to isolate  
10 the set of genes of the biosynthesis cluster.

Our knowledge of the biosynthesis pathways of each of the components of streptogramins is still very incomplete, but the origin of the different parts of each molecule has been identified by radioactive  
15 labelling (Kingston et al. 1983). Thus, the A-type components are made up of two regions originating from the condensation of acetates and several amino acids such as serine and glycine, for example. As regards the B-type components, studies have shown that all the  
20 amino acids present in the peptide chain are derived from natural amino acids (Hook and Vining 1973). However, no polypeptide involved in these pathways has, to date, been purified in sufficient amounts to permit its molecular characterization, and no biosynthesis  
25 gene has been described. In the process of biosynthesis of the B-type components, two parts may be distinguished:

- 1) Synthesis of the precursors, or of their

analogues, of the macrocycle: 3-hydroxypicolinic acid, L-2-aminobutyric acid, p-dimethylamino-L-phenylalanine, 4-oxo-L-pipecolic acid, L-phenylglycine.

2) Formation of the macrocycle from the precursors mentioned above, L-threonine and L-proline, or their analogues, with possible modification of these precursors or peptide N-methylation.

To date, only the probable metabolic origin of the precursors of the macrocycle of the B-type components has been determined by studies using labelled isotopes (Reed et al., 1986, Molinero et al., 1989, Reed et al., 1989).

The present invention results from the purification of polypeptides participating in the biosynthesis of streptogramins, as well as from the cloning of genes whose product participates in the biosynthesis of streptogramins. The term biosynthesis of streptogramins is understood to comprise the regulatory genes and the genes conferring resistance on the producing microorganisms. Thus, the present invention makes it possible to increase the levels of production of these metabolites by means of recombinant DNA techniques. Another benefit of the present invention lies in the possibility, by construction of mutants blocked in the different steps of this biosynthesis, of producing synthesis intermediates for each of the two components. These intermediates may serve as substrates for further modification for

chemical, biochemical, enzymatic or microbiological means. Similarly, isolation of the biosynthesis genes makes it possible, by gene transfer between producing strains, to manufacture hybrid antibiotics having pharmacologically advantageous properties (Hopwood et al., 1985a, Hopwood et al., 1985b, Hutchinson et al. 1989). Another benefit of the present invention lies in the fact that it provides a better knowledge of the biosynthesis pathways of the metabolites classed as streptogramins. In effect, the invention enables bacterial or fungal strains to be constructed in which one or more proteins participating in the biosynthesis of streptogramins is/are expressed under the control of suitable expression signals. Such strains may then be used to carry out bioconversions. These bioconversions may be carried out either using whole cells, or using acellular extracts of the said cells. These bioconversions may enable a streptogramin to be converted to a derived form with an enzyme of a biosynthesis pathway. For example, pristinamycin IIB may be converted in this manner to pristinamycin IIA. The same reasoning may be applied to any biosynthesis intermediate.

A first subject of the invention hence relates to a nucleotide sequence coding for a polypeptide involved in the biosynthesis of streptogramins.

More especially, several genes whose product

participates in the biosynthesis of streptogramins have been isolated from Streptomyces pristinaespiralis.

Since the streptogramins produced by this strain are more commonly designated by the term pristinamycins

5 (see Table 1), in what follows, reference will be made in some cases to genes for the biosynthesis of pristinamycins. However, it is clear that the results obtained apply to all the streptogramins.

Pristinamycins I and II correspond, respectively, to  
10 the B and A components of streptogramins. Molecules of the pristinamycin II family and of the pristinamycin I family hence designate in what follows the A and B components of streptogramins, respectively.

The present invention describes in particular  
15 the isolation and characterization of the snaA, snaB, snaC, snaD, papA, papM, samS, snbA, snbC, snbD, snbE and snbR genes. These genes were isolated from a library of genomic DNA of S.pristinaespiralis. This library was obtained by partial digestion of genomic  
20 DNA S.pristinaespiralis with the restriction enzyme Sau3A. Large DNA fragments, from 40 to 50 kb on average, were cloned into cosmid pHC79 (Hohn, B., and Collins, J.F., 1980). After in vitro encapsidation, E.coli strains HB101 (Boyer et Roulland-Dussoix, 1969)  
25 and DH1 (Low, 1968) were transfected. The DNA library of S.pristinaespiralis thus occurs in two different strains of E.coli.

The snaA, snaB and samS (initially designated

SnaC genes are present on cosmid pIBV1 (Figure 4). The product of the snaA and snaB genes, corresponding to the polypeptides SnaA and SnaB, participates in the final step of biosynthesis of the II component of pristinamycins (conversion of pristinamycin IIB to pristinamycin IIA), corresponding to the oxidation of the 2,3 bond of D-proline. These two polypeptides constitute the two subunits of pristinamycin IIA synthase, the purification of which is described in the present invention. The product of the samS gene is considered to participate in the synthesis of SAM (methyl group donor) from ATP and methionine. The A component of most streptogramins is, in effect, methylated at C-4 (Figure 1), and this methyl has been described (Kingston et al., 1983) as being derived from the methyl of methionine, very probably via a methylation reaction with SAM. The samS gene is hence considered to code for a SAM synthase (SamS; EC. 2.5.1.6) which is specific to the biosynthesis pathway of pristinamycins.

The snbA, snbR, papA and papM genes are present on cosmid pIBV2 (Figure 5). The snbA gene corresponds, on the basis of the biochemical studies presented in Example 5, to the first step for synthesis of pristinamycins I. This comprises activation of the first acid of the chain, 3-hydroxypicolinic acid, by adenylation. The snbR gene might participate in the transport of molecules of the pristinamycin I (or

possibly pristinamycin II) family out of the cell after synthesis, thereby conferring a resistance to this component on the producing strain. The papA gene corresponds, on the basis of sequence analyses (Example 8.8) and the study of a mutant disrupted in this gene (Example 9.3), to a gene for the biosynthesis of para-aminophenylalanine from chorismate. para-Aminophenylalanine is then dimethylated by the product of the papM gene, an N-methyltransferase described in the present invention, to form para-dimethylaminophenylalanine, which is then incorporated in pristinamycin IA. The papA and papM genes hence participate in the synthesis of one of the precursors of pristinamycin IA.

The snaA, snaD, snbC, snbD and snbE genes are present on cosmid pIBV3 (Figure 6), which hence adjoins cosmid pIBV1 on which the snaA gene is already present. The snaD gene codes, on the basis of analysis of its sequence (Example 8.9) and the study of a mutant disrupted in this gene (Example 9.5), for a peptide synthase involved in the biosynthesis of pristinamycin II. The snbC gene, whose product is described in the present invention, participates in the incorporation of ~~threonine~~ and aminobutyric acid residues in the peptide chain of pristinamycin IA. The snbD gene, whose product is also described in the present invention, is involved in the incorporation of proline and para-dimethylaminophenylalanine residues in the peptide chain of pristinamycin IA. It also governs the

N-methylation of the peptide bond between these 2 residues. Lastly, the snbE gene, whose product is also described in the present invention, participates in the incorporation of the last two residues of pristinamycin IA, namely phenylglycine and 4-oxopipericolic acid.

The snaC gene is present on cosmid pIBV4 (Figure 7). It codes for an FMN:NADH oxidoreductase, also designated FMN reductase, described in the present invention and which supplies pristinamycin IIA synthase with FMNH<sub>2</sub> from FMN and NADH. The snaC gene hence participates in the final step of the biosynthesis of pristinamycin IIA.

These different genes were subcloned from their cosmid of origin and their nucleic acid sequences were determined. The snaA, snaB and snaS genes were subcloned on a 6-kb BamHI-BamHI fragment, a portion of which was sequenced (SEQ ID no. 1). The snbA gene was subcloned in a 5.5-kb EcoRI-BglII fragment, a portion of which was sequenced (SEQ ID no. 5). The snbR gene was subcloned in a 4.6-kb BglII-BglII fragment, a portion of which was sequenced (SEQ ID no. 6). A portion of the papA gene was subcloned in a 3.4-kb XhoI-XhoI fragment, a portion of which was sequenced (SEQ ID no. 9). The papM gene was subcloned in a 4.1-kb PstI-PstI fragment, a portion of which was sequenced (SEQ ID no. 10). A portion of the snaD gene was subcloned in a 1.5-kb BamHI-SstI fragment, a portion of which was sequenced (SEQ ID no. 8). A portion of the

snbC gene was subcloned on a 6.2-kb SphI-SphI fragment, 2 regions of which were sequences (SEQ ID nos. 11 and 12). A portion of the snbD gene was subcloned on an 8.4-kb SphI-SphI fragment, 2 regions of which were  
5 sequenced (SEQ ID Nos. 13 and 14). A portion of the snbE gene was subcloned on a 6.6-kb SphI-SphI fragment, 2 regions of which were sequenced (SEQ ID Nos. 15 and 16). The snaC gene was subcloned in a 4-kb BamHI-BamHI fragment, a portion of which was sequenced (SEQ ID  
10 no. 7).

The proximity of the snaA, snaB, snaD, samS, snbC, snbD and snbE genes on the one hand, as well as the snbA, snbR, papA and papM genes, confirms the cluster localization of the genes for biosynthesis of  
15 the A and B components of streptogramins. Furthermore, the 4 cosmids described in the present invention are grouped together in a region of the chromosome whose size is estimated at 200 kb by pulsed-field electrophoresis, equivalent to 3% of the total genome  
20 (7500 kb) of Streptomyces pristinaespiralis (Example 13). It is hence obvious that the regions surrounding the genes identified in the present invention (snaA, snaB, snaD, samS, snbC, snbD and snbE; snbA, snbR, papA and papM; snaC) contain the other genes of the  
25 pristinamycin biosynthesis cluster, and that these genes may be used to localize the other genes for the biosynthesis of streptogramins.

Preferably, the subject of the invention is a

nucleotide sequence chosen from:

(a) all or part of the snaA (SEQ ID no. 2),  
snaB (SEQ ID no. 3), snaC (SEQ ID no. 7), snaD (SEQ ID  
no. 8), papA (SEQ ID no. 9), papM (SEQ ID no. 10), samS  
5 (SEQ ID no. 4), snbA (SEQ ID no. 5), snbC (SEQ ID nos.  
11 and 12), snbD (SEQ ID nos. 13 and 14), snbE (SEQ ID  
nos. 15 and 16) and snbR (SEQ ID no. 6) genes,

(b) the sequences adjacent to the genes (a)  
constituting the biosynthesis clusters and coding for  
10 the polypeptides involved in the biosynthesis of  
streptogramins,

(c) the sequences which hybridize with all or  
part of the genes (a) or (b) and which code for a  
polypeptide involved in the biosynthesis of  
15 streptogramins, and

(d) the sequences derived from the sequences  
(a), (b) and (c) owing to the degeneracy of the genetic  
code.

Still more preferably, the subject of the  
20 invention is the nucleotide sequences represented by  
the snaA (SEQ ID no. 2), snaB (SEQ ID no. 3), snaC (SEQ  
ID no. 7), snaD (SEQ ID no. 8), papA (SEQ ID no. 9),  
papM (SEQ ID no. 10), samS (SEQ ID no. 4), snbA (SEQ ID  
no. 5), snbC (SEQ ID nos. 11 and 12), snbD (SEQ ID nos.  
25 13 and 14), snbE (SEQ ID nos. 15 and 16) and snbR (SEQ  
ID no. 6) genes.

Another subject of the invention relates to  
any recombinant DNA comprising a gene for the

biosynthesis of streptogramins. More preferably, this is a recombinant DNA comprising all or part of cosmids pIBV1, pIBV2, pIBV3 or pIBV4 as shown in Figures 4 to 7, or all or part of sequences which hybridize with  
5 cosmids pIBV1 to pIBV4 or with fragments of these latter.

In a preferred embodiment of the invention, the nucleotide sequences defined above form part of an expression vector, which can be autonomously  
10 replicating or integrative.

As stated above, although the invention is more especially illustrated with the genes for the biosynthesis of pristinamycin, it is clear that the results obtained apply to all streptogramins.

15 More especially, the techniques developed in the present invention for purifying proteins or cloning genes for the biosynthesis of streptogramins from S. pristinaespiralis may be applied to other microorganisms producing streptogramins (see Table 1).

20 Thus, the purification of an enzymatic activity from S. pristinaespiralis makes it possible to purify the same activity from another strain producing streptogramin. The present invention may hence be applied to the cloning of genes for the biosynthesis of  
25 streptogramins from any producing microorganism, by purification of a protein participating in the biosynthesis and then, using the NH<sub>2</sub>-terminal sequence thereof, synthesis of an oligonucleotide probe which

enables the corresponding gene to be cloned. Chromosome walking then enables the whole biosynthesis cluster to be identified.

Furthermore, from the genes identified in the present application, it is possible, by hybridization, to clone the genes for the biosynthesis of streptogramins directly from the DNA of another producing microorganism. In effect, the genes for the biosynthesis of pristinamycins hybridize strongly with those for the other streptogramins. It is thus possible to clone, by hybridization, the genes for the biosynthesis of streptogramins using as a probe the sna, snb or pap genes, or fragments of the latter, or fragments adjacent to these containing, as is shown in the present invention, other sna and snb genes. This is due to the fact that: 1) the streptogramins produced by the different microorganisms have identical or similar structures (see Figure 3), 2) the genes for the biosynthesis of streptogramins are organized in clusters, and 3) the enzyme systems responsible for this biosynthesis do not have an absolute specificity for their substrates.

Moreover, the cloning of genes involved in the biosynthesis of streptogramins may also be carried out using degenerate oligonucleotides, prepared from the sequences of the sna or snb genes mentioned above, or fragments of these genes, or fragments adjacent to these genes. It is thus possible to take one's pick of

the genes for the biosynthesis of the A and B components of the different strains producing streptogramins. These strains can belong to the genus Streptomyces, and also to other genera (see Table 1).

5 In addition, if the genomic DNA of the starting strains used has a G+C composition different from that observed in Streptomyces, the probes used may be synthesized with a codon bias specific to the genus or species from which it is desired to isolate the DNA.

10 Another subject of the present invention relates to the polypeptides resulting from the expression of the nucleotide sequences defined above. More especially, the present invention relates to polypeptides comprising all or part of the polypeptides

15 SnaA (SEQ ID no. 2), SnaB (SEQ ID no. 3), SnaC (SEQ ID no. 7), SnaD (SEQ ID no. 8), PapA (SEQ ID no. 9), PapM (SEQ ID no. 10), SamS (SEQ ID no. 4), SnbA (SEQ ID no. 5), SnbC (SEQ ID nos. 11 and 12), SnbD (SEQ ID nos. 13 and 14), SnbE (SEQ ID no. 15 and 16) and SnbR (SEQ ID

20 no. 6) or of derivatives of these. Within the meaning used in the present invention, the term derivative denotes any molecule obtained by modification of a genetic and/or chemical nature of the peptide sequence. Modification of a genetic and/or chemical nature is

25 understood to mean any mutation, substitution, deletion, addition and/or modification of one or more residues. Such derivatives may be generated for different purposes, such as, in particular, that of

increasing the affinity of the peptide for its substrate(s), that of improving its levels of production, that of increasing its resistance to proteases, that of increasing and/or modifying its activity, or that of endowing it with novel biological properties. Among derivatives resulting from an addition, there may be mentioned, for example, chimeric polypeptides containing an additional heterologous portion attached to one end. The term derivative also comprises polypeptides homologous to the polypeptides described in the present invention and originating from other cell sources, and in particular from strains producing streptogramins.

The subject of the invention is also any recombinant cell containing a nucleotide sequence or a vector as defined above. The recombinant cells according to the invention can equally well be eukaryotic cells or prokaryotic cells. Among eukaryotic cells which are suitable, animal cells, yeasts or fungi may be mentioned. In particular, as regards yeasts, yeasts of the genus Saccharomyces, Kluyveromyces, Pichia, Schwanniomyces or Hansenula may be mentioned. As regards animal cells, COS, CHO, C127 cells, Xenopus eggs, and the like, may be mentioned. Among fungi, special mention may be made of Micromonospora, Aspergillus ssp. or Trichoderma ssp. As prokaryotic cells, it is preferable to use the following bacteria: Actinomycetes, and Streptomyces in particular, E. coli

(Example 11), Bacillus. Preferably, the recombinant cells of the invention are chosen from cells producing streptogramins (see Table 1). The recombinant cells of the invention may be obtained by any method which  
5 enables a foreign nucleotide sequence to be introduced into a cell. It can be, in particular, transformation, electroporation, conjugation, protoplast fusion or any other technique known to a person skilled in the art.

A further subject of the invention is a  
10 method for producing a polypeptide involved in the biosynthesis of streptogramins, according to which a recombinant cell as defined above is cultured and the polypeptide produced is recovered.

The subject of the invention is also the use  
15 of a recombinant cell as defined above, expressing at least one polypeptide involved in the biosynthesis of streptogramins, in a bioconversion reaction. In particular, these cells can enable a streptogramin to be converted into a derived form. For example,  
20 pristinamycin IIB can be converted in this manner to pristinamycin IIA. The same reasoning may be applied to any biosynthesis intermediate. These cells can also enable hybrid antibiotics having advantageous pharmacological properties to be manufactured (Hopwood  
25 et al. 1985a, Hopwood et al. 1985b, Hutchinson et al. 1989). These bioconversions may be carried out either using whole cells, or using acellular extracts of the said cells.

Another subject of the invention relates to the use of a nucleotide sequence as defined above for amplifying streptogramin production. The invention also relates to a method for producing streptogramins, according to which one or more nucleotide sequences according to the invention is/are introduced and/or amplified in a cell producing streptogramins or which is potentially a producer of streptogramins, the said cell is cultured under conditions of streptogramin production, and the streptogramins produced are recovered.

The overexpression of certain genes involved in the biosynthesis can enable the streptogramin A and/or B production of the producing strains to be increased. This overproduction may be carried out in several strains: either strains which produce only molecules of the streptogramin A family, or strains which produce only molecules of the streptogramin B family, or strains which produce both the A and B components. These overexpressions can result from an increase in the level of synthesis, and hence in the productivity, of the A and/or B components, either in an Erlenmeyer, or in small fermenters, or in large industrial fermenters. Moreover, the specific overexpression of a gene involved in the biosynthesis of an A or B component also makes it possible to vary the % of A and B components produced by the strain, and thus to obtain a better synergy between these

molecules. In addition, the biosynthesis genes isolated from a microorganism producing streptogramins may be used to amplify production in another producing microorganism.

5           Another subject of the invention relates to a method for preparing cells blocked in a step of the pathway of biosynthesis of streptogramins, according to which a mutagenesis is performed on at least one gene of the biosynthesis pathway, on a cell producing  
10 streptogramins.

          Preferably, the mutagenesis is performed in vitro or in situ, by suppression, substitution, deletion and/or addition of one or more bases in the gene in question, or by gene disruption.

15           Another aspect of the present invention lies, in effect, in the construction of mutants blocked in certain steps of biosynthesis of streptogramins. The value lies, on the one hand in the study of the functionality of the mutated proteins, and on the other  
20 hand in the production of strains producing biosynthesis intermediates. These intermediates may be modified, where appropriate after separation, either by adding particular components to the production media, or by introducing into the strains thus mutated other  
25 genes capable of modifying the intermediate by acting as a substrate for them. These intermediates may thus be modified by chemical, biochemical, enzymatic and/or microbiological means. In this context, the mutant

SP92::pVRC505 of S. pristinaespiralis strain SP92 was constructed: S. pristinaespiralis SP92::pVRC505 was isolated by homologous integration in the snaA gene of a suicide plasmid pVRC505, constructed from the vector pDH5 and a fragment internal to the snaA gene. The following mutants were also constructed: SP92 samS::OamR; SP92::pVRC508; SP92::pVRC404 and SP92::pVRC1000 (Example 9).

The invention hence also relates to a method for preparing an intermediate of the biosynthesis of streptogramins, according to which:

- a cell blocked in a step of the pathway of biosynthesis of streptogramins is prepared as described above,

- the said cell is cultured, and
- the accumulated intermediate is recovered.

The invention also relates to a method for preparing a molecule derived from streptogramins, according to which:

- a cell blocked in a step of the pathway of biosynthesis of streptogramins is prepared as described above,

- the said cell is cultured, and
- the intermediate accumulated by this cell is modified, where appropriate after separation of the culture medium.

The present invention is illustrated by means of the examples which follow, which are to be

considered as illustrative and non-limiting.

EXAMPLE 1: Isolation of total DNA of

Streptomyces pristinaespiralis strain SP92

This example illustrates how S.  
10 pristinaespiralis SP92 DNA may be purified.

S. pristinaespiralis strain SP92 is derived  
from S. pristinaespiralis strain DS5647 (ATCC25486).

50 ml of YEME medium (34% sucrose, 5 mM MgCl<sub>2</sub>,  
0.25% glycine (D. Hopwood et al. 1985)) are inoculated  
15 with 10<sup>8</sup> S. pristinaespiralis SP92 spores, and the  
culture is incubated for 40 hours at 30°C with stirring  
at 280 rpm.

The mycelium is harvested and washed with  
15 ml of 10.3% sucrose. Approximately 1 g of the  
20 mycelium pellet is taken up with 5 ml of TE  
supplemented with 34% of sucrose, to which are added  
1 ml of lysozyme at a concentration of 50 mg/ml in  
10 mM Tris-HCl solution pH 8.0 and 1 ml of 0.25 M EDTA  
pH 8.0. After incubation at 30°C for a period of 30 to  
25 60 min, the mixture is clarified by adding 0.8 ml of  
10% sarkosyl. 2 ml of 0.25 M EDTA pH 8.0, 10 ml of TE,  
18 g of CsCl and 1.2 ml of ETB at a concentration  
10 mg/ml are then added. The preparation is

ultracentrifuged overnight at 55,000 rpm at 20°C.

The chromosomal DNA, present in the CsCl gradient in the form of a band, is recovered using a Pasteur pipette. The ETB is removed by several washes  
5 with a solution of isopropanol saturated with TE buffer, 5 M NaCl. The DNA is precipitated by adding 3 volumes of TE and 4 volumes of isopropanol. After washing with 70% ethanol, the DNA is taken up in a suitable volume of TE. The total amount of DNA obtained  
10 varies between 250 and 500 µg per g of mycelium.

#### EXAMPLE 2: Isolation of E. coli plasmid DNA

This example illustrates how E. coli plasmid DNA is prepared from recombinant strains of E. coli.

##### 2.1. Preparation of E.coli plasmid DNA in 15 large amounts

This example illustrates how maxi pre-  
parations of plasmid DNA are produced in E. coli.

This preparation is performed using a 500 ml culture in LB medium containing 150 µg/ml of  
20 ampicillin. The extraction protocol is derived from the methods described by Birnboim and Doly (1979) and Ish-Horowicz and Burke (1981), and is described in Maniatis et al. (1989).

After this extraction, the plasmid DNA is  
25 purified using a CsCl gradient as described by Maniatis et al. (1989). The plasmid DNA is then precipitated by adding 3 volumes of TE and 4 volumes of isopropanol. After centrifugation, the pellet is taken up in 0.5 to

1 ml of TE.

2.2. Preparation of E. coli plasmid DNA in small amounts

This example illustrates how minipreparations of plasmid DNA are produced in E. coli.

This preparation is carried out using 1.5 ml of culture in LB medium containing 150 µg/ml of ampicillin. The procedure is that described by Birnboim and Doly (1979).

EXAMPLE 3: Construction of the genomic DNA library of S. pristinaespiralis SP92 in E. coli and preparation of hybridization membranes

This example illustrates how a genomic DNA library of S. pristinaespiralis SP92 is produced in E. coli.

3.1. Preparation of genomic DNA fragments

This example illustrates how high molecular weight genomic DNA fragments may be prepared.

Total DNA of the strain SP92, prepared as described in Example 1, is partially digested with Sau3A (New England Biolabs, Beverly, MA. 01915-5510 USA) in the buffer recommended by the supplier: 100 mM NaCl, 10 mM Tris-HCl (pH7.5), 10 mM MgCl<sub>2</sub>, 100 µg/ml BSA. The amount of enzyme used to obtain high molecular weight DNA fragments was determined empirically. Approximately 0.025 enzyme units are used to digest 1 µg of total DNA for 20 min at 37°C. The reaction is then stopped by incubation for 15 min at 65°C, and the

enzyme is removed by adding an equal volume of phenol/  
chloroform. After centrifugation, the supernatant  
containing the partially digested total DNA is  
precipitated by adding 0.3 M final sodium acetate and  
5 2.5 volumes of ethanol.

Approximately 100 µg of total DNA are  
digested in this way, and DNA fragments between 30 and  
50 kb in size are isolated with a 10-40% sucrose  
gradient. Their size is verified by electrophoresis on  
10 0.4% agarose gel.

### 3.2. Preparation of cosmid pHC79

This example illustrates how cosmid pHC79 is  
prepared from E. coli.

Cosmid pHC79 (Hohn, B. and Collins, 1980)  
15 comprises a portion of pBR322 (Bolivar, F. et al.,  
1977), the cro-cII region of λ and the region  
containing the cos sequence of Charon 4A (Blattner,  
F.R. et al., 1977).

Extraction of the cosmid was carried out as  
20 described in Example 2.1., from an E. coli strain TG1  
(K12, Δ(lac-pro) supE thi hsd DS F' traD36 proA<sup>+</sup>B<sup>+</sup> lacIq  
LacZ ΔM15, Gibson, 1984).

500 ng of cosmid pHC79 are digested with  
BamHI (New England Biolabs, Beverly, MA. 01915-5510  
25 USA) in 20 µl of buffer comprising 150 mM NaCl, 6 mM  
Tris-HCl pH 7.9, 6 mM MgCl<sub>2</sub>, 6 mM 2-mercaptoethanol,  
100 µg/ml BSA.

### 3.3. Ligation of the DNA fragments and the cosmid

This example illustrates how the fragments of the S. pristinaespiralis SP92 genome originating from an Sau3A digestion may be ligated with the BamHI-linearized vector pHC79.

Approximately 150 ng of cosmid linearized as described above were precipitated by means of ethanol with 350 ng of fragments of total DNA of S. pristinaespiralis SP92 prepared as described in Example 3.2. The pellet was taken up in 10  $\mu$ l of ligation buffer: 50 mM Tris-HCl pH 7.8, 10 mM MgCl<sub>2</sub>, 20 mM DTT, 1 mM ATP, 50  $\mu$ g/ml of BSA, and 0.5  $\mu$ l of T4 DNA ligase at a concentration of 400,000 units per ml (New England Biolabs, Beverly, MA. 01915-5510 USA) were added. Incubation was carried out overnight at 15°C.

### 3.4. Carrying out encapsidation in vitro

This example illustrates how the cosmids constructed in 3.3 are encapsidated in vitro.

Encapsidation of the hybrid cosmids after ligation was carried out using the Gigapack II Gold kit developed by Stratagene (Stratagene Cloning Systems, La Jolla, CA 92037, USA).

2  $\times$  4  $\mu$ l of ligation mixture, equivalent to 2  $\times$  70 ng of hybrid cosmids, were encapsidated in vitro according to the procedure described by the supplier.

### 3.5. Transfection of *E. coli* strains DH1 and HB101

This example illustrates how the cosmids are introduced into *E. coli*.

5 Two transfections were carried out in parallel with *E. coli* strains DH1 (F<sup>-</sup> gyrA96 recA1 relA1 endA1 thi-1 hsdR17 supE44L-, Low 1968) and HB101 (F<sup>-</sup> supE44 hsdS20(rB<sup>-</sup>mB<sup>-</sup>) recA13 ara-14 proA2 lacY1 galK2 rpsL20 xyl-5 mtl-1, Boyer and Roulland-Dussoix 1969).

10 The cells were prepared according to the following protocol: a 100-ml preculture is produced in LB medium supplemented with 0.2% maltose and 10 mM MgSO<sub>4</sub> for 4 to 5 hours until the OD<sub>600</sub> reaches a value of 0.8. The culture is then centrifuged, and the pellet is  
15 taken up in 40 ml of 10 mM MgSO<sub>4</sub> and diluted to OD<sub>600</sub> = 0.5 in the same solution. 200 µl of the cell suspension thus prepared are mixed with 100 µl of encapsidation mixture. After 20 min of contact at 37°C, 1 ml of LB is added and the whole is incubated for  
20 1 hour at 37°C. The transfectants are then selected on solid LB medium containing 150 µg/ml of ampicillin. The number of transfectants obtained is approximately 10<sup>4</sup> per µg of recombinant cosmid.

### 3.6. Storage of genomic DNA libraries of *S. pristinaespiralis* SP92

This example illustrates how the genomic DNA libraries of *S. pristinaespiralis* SP92 are stored.

After verification of the average size of the

fragments inserted into cosmid pHC79, approximately 1500 colonies originating from each of the transfections carried out with the strains HB101 and DH1 are subcultured in 96-well microtitration plates containing 200  $\mu$ l of Hogness medium (LB medium supplemented with 8.8% glycerol, 3 mM sodium acetate, 55 mM  $K_2HPO_4$ , 26 mM  $KH_2PO_4$ , 1 mM  $MgSO_4$ , 15 mM  $(NH_4)_2SO_4$ , 150  $\mu$ g/ml ampicillin). These plates are incubated overnight at 37°C and then stored at -80°C.

10        3.7. Preparation of hybridization membranes from genomic libraries of *S. pristinaespiralis* SP92

          This example illustrates how the DNA of the colonies constituting the genomic libraries of *S. pristinaespiralis* SP92 is transferred onto a hybridization membrane.

          These hybridization membranes were produced in duplicate for each of the 2 libraries according to the following protocol:

          The 15 microtitration plates of each library are replicated using a replica plater on LB agar medium containing 150  $\mu$ g/ml of ampicillin. After growth overnight at 37°C, colony transfer is performed onto a Biohyloa-Z<sup>+</sup> membrane (Bioprobe System) according to the following protocol: the membrane is cut to the appropriate size and left in contact with the colonies for 1 min. Denaturation is then performed by soaking the membrane with 0.5 M NaOH, 1.5 M NaCl solution for 5 min, followed by neutralization by soaking the

membrane in 3 M sodium acetate solution for 5 min. The DNA is fixed to the membrane by exposure under a UV lamp for 5 min.

#### EXAMPLE 4

5        4.1. Preparation of chromosomal DNA of *S. pristinaespiralis* strain SP92 and strains derived from SP92 in the form of inserts for pulsed-field electrophoresis

10        This example illustrates how DNA of *S. pristinaespiralis* strain SP92 and strains derived from SP92 is prepared in the form of inserts for pulsed-field electrophoresis.

15        This preparation is made from a mycelium culture obtained in the following manner: 30 ml of YEME medium containing 0.25% of glycine are inoculated with 10<sup>8</sup> spores of the strain under study, and the culture is incubated for 48 hours at 30°C and stirred at 280 rpm in 250-ml Erlenmeyers. The mycelium is then harvested by centrifugation for 10 min at 3800 rpm and washed 20        twice with 10% sucrose. The mycelium pellet is then resuspended in 5 ml of solution I (250 mM EDTA pH 8.0, 20.6% sucrose). To 200 ml of mycelium thereby obtained, 400 ml of a lysozyme solution at a concentration of 50 mg/ml in solution I together with 800 ml of 1% LMP 25        agarose in 25 mM EDTA pH 8 and 10.3 % sucrose, maintained at 42°C, are added. The mixture maintained at 42°C is then poured into the wells of special combs, which are closed with adhesive tape and kept for 30 min

at 4°C. The mixture solidifies, and the 30 to 40 inserts thereby obtained and contained in the wells are carefully removed from the moulds.

The inserts are first rinsed for 30 min at  
5 4°C in a solution containing 25 mM EDTA and 10.3% sucrose. They are then soaked in a solution of 500 mM EDTA, 1% lauryl sarcosyl and 1 mg/ml of proteinase K for twice 24 hours at 50°C, stirring from time to time. The inserts are then washed for 3 times one hour in TE  
10 containing 1 mM PMSF, changing the solution after each wash. The inserts thereby obtained are stored at 4°C for not more than 4 months in 0.5 M EDTA pH 8.0.

4.2. Digestion of inserts of DNA of S. pristinaespiralis strain SP92 and strains derived from  
15 SP92 and analysis by pulsed-field electrophoresis

This example illustrates how chromosomal DNA of S. pristinaespiralis strain SP92 and strains derived from SP92, prepared in the form of inserts as described in Example 4.1., is cut with different restriction  
20 enzymes for pulsed-field electrophoresis.

4.2.1. Digestion of chromosomal DNA in the form of inserts:

..... The inserts are first washed six times in TE, and then incubated twice for one hour in the buffer of  
25 the chosen restriction enzyme. Each insert is then placed in the lid of an Eppendorf tube containing 160 µl of buffer of the restriction enzyme and 40 units of enzyme. The whole is covered with Parafilm, and the

Eppendorf is closed to hold in place the Parafilm which enables any evaporation of the buffer to be avoided. The tubes are incubated at the desired temperature in an incubator overnight.

5           4.2.2. Analysis of digested DNA by pulsed-field electrophoresis:

          The pulsed-field electrophoresis technique chosen for this study is that of the CHEF (Clamped Homogenous Electric Field) system developed by Chu et  
10 al. (1986), which makes it possible to obtain two homogeneous alternating fields oriented at 120° with respect to one another and linear trajectories for the DNA molecules. The apparatus used is the "Pulsafor System" marketed by Pharmacia-LKB.

15           The electrophoretic migration parameters, such as the pulse time and the migration period, were varied so as to obtain an optimal separation of DNA fragments ranging in size between 10 and 2500 kb. The three migration conditions used are as follows: to  
20 separate large fragments from 200 to 1700 kb in size, the chosen migration is 40 hours with a pulse time of 90 seconds; to separate fragments from 50 to 400 kb in size, the chosen migration is 20 hours with a pulse time of 10 seconds followed by 20 hours with a pulse  
25 time of 30 seconds; lastly, to separate smaller fragments from 10 kb to 200 kb in size, the chosen migration is 24 hours with a pulse time of 10 seconds. For these three migration conditions, the voltage is

set at a constant 150 volts, the temperature is maintained at 13°C and the electrophoresis gels contain 1.3% of agarose.

The inserts containing chromosomal DNA of *S. pristinaespiralis* strain SP92 and strains derived from SP92 are digested with the restriction enzymes as described above and are placed in the wells of the electrophoresis gel using two scalpel blades. The molecular weight markers used are "Yeast chromosome PFG marker" and "Lambda Ladder PFG marker" marketed by the company New England Biolabs. Migration is performed under one of the conditions described above and the gel is then stained in a bath of ETB (ethidium bromide) at a concentration of 4 Mg/ml for 20 min and thereafter decolorized in water for 20 min. After the gel is photographed, the DNA fragments are transferred onto a nylon membrane and then hybridized with [ $\alpha$ -<sup>32</sup>P]dCTP-labelled probes as described in Example 9.1.

**EXAMPLE 5: Isolation of cosmids carrying the genes coding for purified proteins involved in the biosynthesis of streptogramins**

This example describes how, starting from a purified protein participating in biosynthesis of pristinamycins and whose NH<sub>2</sub>-terminal sequence or an internal sequence has been established, it is possible to isolate a cosmid carrying the structural gene for this same protein from the genomic libraries produced above, or alternatively to identify the corresponding

structural gene from among the genes carried by the cosmids and which have already been sequenced.

5.1. Isolation of cosmids pIBV1 and pIBV3  
carrying one or both structural genes for the two  
5 subunits of pristinamycin IIA synthase

5.1.1. Identification and purification of one  
of the proteins involved in the final step of the  
synthesis of pristinamycins II: pristinamycin IIA  
synthase

10 As stated in the introduction, the final step  
of synthesis of pristinamycin IIA corresponds to an  
oxidation of the 2,3 bond of D-proline to  
dehydroproline. The protein responsible for this  
activity has been purified to homogeneity, as  
15 illustrated by this example.

5.1.1.A. Assay of pristinamycin IIA synthase  
activity

This example illustrates the assay of an  
activity of the biosynthesis pathway of pristinamycin  
20 IIA which has never before been described and which  
possesses the noteworthy property of being expressed  
only during the period of production of pristinamycins.  
The enzyme in question is pristinamycin IIA synthase,  
which catalyses the conversion of pristinamycin IIB to  
25 pristinamycin IIA by oxidation of the D-proline residue  
of pristinamycin IIB to a 2,3-dehydroproline residue  
(Figure 8) in the presence of molecular oxygen and  
FMN<sub>2</sub>. The enzyme fractions to be assayed (0.002 to

0.005 units) are incubated for 1 h at 27°C in a total volume of 500 µl of 50 mM bis-tris propane buffer pH 6.8 containing NADH (500 µM), FMN (5 µM), pristinamycin IIB (20 µM) and 0.02 units of FMN reductase (Boehringer Mannheim).

The pristinamycin IIA formed is assayed by HPLC after incubation is stopped by adding 500 µl of 0.1 N hydrochloric acid and 500 µl of acetonitrile and centrifugation of the sample for 5 min at 5000 g. 150 µl of the centrifugation supernatant are injected onto a 15-cm Nucleosil 5-C8 column eluted with a mixture of 34% of acetonitrile and 66% of 0.1 M phosphate buffer pH 2.9. Pristinamycins IIA and IIB are detected by means of their UV absorbance at 206 nm.

The unit of enzymatic activity is defined as the amount of enzyme needed to synthesize 1 µmol of pristinamycin IIA per hour under the conditions described.

#### 5.1.1.B. Purification of S. pristinaespiralis SP92 pristinamycin IIA synthase

This experiment illustrates how an enzyme of S. pristinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IIA may be purified.

Using the assay described above in Example 5.1.1.A, the purification of pristinamycin IIA synthase is carried out as described below taking care to freeze and store the active fractions at -30°C between

successive steps if necessary.

150 g of a centrifugation pellet, washed with 0.1 M phosphate buffer pH 7.2 containing 10% v/v of glycerol, of an S. pristinaespiralis SP92 culture

5 harvested at the beginning of the pristinamycin production phase are taken up with 450 ml of 50 mM bis-tris propane buffer pH 6.8 containing 5 mM DTT and 0.2 mg/ml of lysozyme. The suspension thereby obtained is incubated for 45 minutes at 27°C and then

10 centrifuged at 50,000 g for 1 hour. The crude extract thereby collected is fractionated by ammonium sulphate precipitation. The protein fraction precipitating at between 40 and 55% saturation is desalted on a column of Sephadex G-25 Fine, and then injected (100 mg per

15 injection) in pH 6.8 50 mM bis-tris propane buffer, 1 mM DTT onto a monoQ HR 10/10 column. The proteins are eluted with a linear KCl gradient (0 to 0.5 M). The fractions containing the enzymatic activity (detected by means of the test described in Example 5.1.1.A) are

20 pooled and concentrated to 20 ml on Centriprep 10. After dilution with one volume of pH 6.8 50 mM bis-tris propane buffer, 1 mM DTT containing 2 M ammonium sulphate, the proteins are chromatographed (22.5 mg per injection) on a Phenyl Superose HR 10/10 column with a

25 decreasing ammonium sulphate gradient (1.0 M to 0 M). The best fractions containing the desired activity are pooled, reconcentrated to 1 ml on Centriprep 10 and then applied (200 µl per injection) to a Bio-Sil

SEC 250 column. The activity peak is detected in this technique at a molecular weight centred at 77,000. The fraction containing the activity is injected onto a MonoQ HR 5/5 column in pH 6.8 50 mM bis-tris propane buffer, DTT 1 mM eluted with a linear KCl gradient (0 to 0.5 M).

After this step, the enzyme is pure and, in SDS-PAGE electrophoresis, two subunits of molecular weight estimated at 35,000 and 50,000 are detected. They are separated on a 25-cm Vydac C4 column eluted with a linear gradient of from 30 to 50% of acetonitrile in water containing 0.07% of trifluoroacetic acid.

Table: Purification of pristinamycin IIA synthase

Purification step	Vol. (ml)	Protein (mg)	Sp.Act. $\mu\text{mol/h/mg}$	Yield (%)	Purification factor
Crude extract	490	1690	0.14	100	1
40-45% A.S.	60	1050	0.19	85	1.4
MonoQ 10/10	95	45	3.0	58	21
Phenyl Superose	8	2.8	12	14	86
Bio-sil SEC	5	1.3	18	14	130
MonoQ 5/5	10	0.7	23	10	160

The purification factor is calculated from the increase in specific activity of the fractions during the purification.

#### 5.1.2. Production of oligonucleotides from

the protein sequences:

This example describes how, starting from the NH<sub>2</sub>-terminal sequences of the two subunits of pristinamycin IIA synthase purified as described in Example 5.1.1.B., it is possible to synthesize oligonucleotides. The two subunits of pristinamycin IIA synthase are referred to as SnaA and SnaB, and correspond to polypeptides of molecular weights 50,000 and 35,000, respectively, as described in Example 5.1.1.B.

The NH<sub>2</sub>-terminal sequences of the proteins SnaA and SnaB, corresponding to the subunits of pristinamycin IIA synthase, were deduced by microsequencing. This is carried out by the Edman degradation technique, using an automated sequencer (Applied Biosystems model 407A) coupled to an HPLC apparatus for identification of the phenylthiohydantoin derivatives. About thirty residues were determined for each of them.

Protein SnaA: (see residues 2 to 29 on SEQ ID No. 2)  
T A P(R)(R,W)R I T L A G I I D G P G G H V A A(W)R H P (A) T  
Protein SnaB: (see residues 2 to 31 on SEQ ID No. 3)

T A P T L V A T L D T R G P A A T L G T I T(R)A V(R)A A E A

Moreover, sequences internal to these two polypeptides were determined after trypsin digestion of SnaA and SnaB and purification of the fragments obtained on a Vydac C18 HPLC column. The following internal sequences were found:

Protein SnaA: (see residues 365 to 384 on SEQ ID No. 2)

G A D G F N I D F P Y L P G S A D D F V

Protein SnaB: (see residues 122 to 136 on SEQ ID No. 3)

G L(-)D S F D D D A F V H D R

5                   From the underlined regions in each of the  
sequences of the fragments internal to the proteins  
SnaA and SnaB, and in accordance with the degeneracy of  
the genetic code specific to Streptomyces (see Example  
8), the following mixtures of oligonucleotides were  
10 synthesized with a Biosearch 8600 automated  
synthesizer. They were then purified by the technique  
already described (Sawadogo M. and Von Dyke M. W.,  
1991). The snaA and snaB genes denote the structural  
genes for the proteins SnaA and SnaB, respectively.

15                   Mixture corresponding to the underlined  
portion of the internal sequence of SnaA:

20                   ATC GAC TTC CCC TAC CTC CCC GG  
                          T    T    G    T    G    G  
                                  A  
                                  T

Mixture corresponding to underlined portion  
of the internal sequence of SnaB:

25                   TTC GAC GAT GAT GCA TTC GTC CAT GAC  
                          C    C    T           G    C  
                                  C  
                                  G

5.1.3. Labelling of the mixtures of synthetic  
oligonucleotides and hybridization with the genomic DNA  
libraries of the strain SP92

30                   This example describes how oligonucleotides  
specific for a gene for the biosynthesis of

pristinamycins may be radioactively labelled and then hybridized with membranes onto which DNA of genomic libraries of S. pristinaespiralis SP92 has been transferred.

5            Labelling of the oligonucleotides is carried out by transfer at the 5'-terminal position of the [ $\gamma$ - $^{32}$ P]phosphate group of ATP with T4 polynucleotide kinase. This labelling is carried out as described in Maniatis et al. (1989). After labelling, the  
10 oligonucleotides are used without purification.

Approximately 2 x 500 ng of each mixture of oligonucleotides were labelled in this way with  $^{32}$ P and were used to hybridize each of the two libraries.

Hybridization of the membranes of each  
15 library is carried out according to a protocol derived from those developed by Meinkoth, J. and Wahl, G. (1984) and Hames, B.D. and Higgins, S.J. (1985): the 15 membranes are prehybridized for 3 hours at 50°C in 40 ml of a solution containing: Denhardt (x5) [Denhardt  
20 (x100): 2% (w/v) Ficoll, 2% (w/v) polyvinylpyrrolidone, 2% (w/v) BSA)], SSC (x5) [SSC (x20): 3 M NaCl, 0.3 M sodium citrate), 50 mM NaPO<sub>4</sub>, pH 6.5, 0.1% SDS, 250 µg/ml salmon sperm DNA].

Hybridization is then carried out overnight  
25 at 50°C in 20 ml of the same solution to which the 500 ng of labelled oligonucleotides are added.

The filters are then washed in a solution of SSC (x6) and 0.5% SDS, twice for 30 min at room

temperature and then empirically at gradually higher temperatures (50 to 65°C). The temperature of these latter washes is gradually increased after successive autoradiographic exposures in order to determine the  
5 specificity of the hybridizing clones with the mixtures of oligonucleotides.

5.1.4. Isolation of cosmids pIBV1 and pIBV3 and determination of the regions containing the snaA and snaB genes

10 This example illustrates how it is possible to isolate cosmids constructed as described in Example 3 containing genes for the biosynthesis of pristinamycins.

Cosmids pIBV1 and pIBV3 were isolated from  
15 two clones originating, respectively, from the library produced in the strain HB101 and from the library produced in the strain DH1 which hybridized with both mixtures of oligonucleotides simultaneously for pIBV1 and with the mixture of oligonucleotides originating  
20 from the internal sequence of the protein SnaA for pIBV3.

These cosmids were purified as described in Example 2. Cosmids pIBV1 and pIBV3 contain, respectively, a genomic DNA insert of S.  
25 pristinaespiralis SP92 whose sizes were estimated, respectively, at 30 kb and 34 kb. Maps (Figures 4 and 6) were established from digestions with different restriction enzymes, according to the protocols of the

supplier (New England Biolabs, Beverly, MA. 01915-5510 USA).

Southern hybridizations of pIBV1 and pIBV3 DNA, digested by means of different enzymes, with the mixtures of oligonucleotides enabled the region of this cosmid containing the snaA and/or snaB genes to be identified.

Southern hybridization was carried out as described in Maniatis et al. (1989). After separation of the restriction fragments by electrophoresis on 0.8% agarose gel, the DNA is transferred onto a Biohylon Z<sup>+</sup> membrane (Bioprope System). Hybridization of the DNA thus transferred onto the membranes with the mixtures of oligonucleotides was carried out as described in Example 5.1.3.

These Southern hybridizations enabled it to be shown that cosmid pIBV1 possessed a 6-kb BamHI fragment containing the sequences homologous to the probes synthesized in Example 5.1.2 (originating from the proteins SnaA and SnaB), as well as a 2.5-kb EcoRI fragment internal to the BamHI fragment containing the sequences homologous to the probes originating exclusively from the protein SnaA. Furthermore, the hybridization signals obtained with cosmid pIBV3 showed that it possessed only the 2.5-kb EcoRI fragment containing the sequences homologous to probes originating exclusively from the protein SnaA.

5.2. Isolation of cosmid pIBV2 containing the structural gene for 3-hydroxypicolinic acid:AMP ligase (snbA)

5 This example illustrates how it is possible to obtain a cosmid as constructed in Example 3 containing at least one gene for the biosynthesis of pristinamycins I.

10 5.2.1. Identification and purification of the protein involved in the activation of 3-hydroxypicolinic acid

This example illustrates how the protein responsible for the activation of 3-hydroxypicolinic acid may be purified to homogeneity from S. pristinaespiralis SP92.

15 5.2.1.A. Assay of 3-hydroxypicolinic acid:AMP ligase

20 This example illustrates the assay of an activity of the biosynthesis pathway of pristinamycin IA which has never before been described and which possesses the noteworthy property of being expressed only during the period of production of pristinamycins. The enzyme in question is 3-hydroxypicolinic acid:AMP ligase, which catalyses the formation of the adenylate of 3-hydroxypicolinic acid (Figure 9) from this free  
25 acid and ATP in the presence of MgCl<sub>2</sub>.

The enzyme fractions to be assayed (0.002 to 0.020 units) are incubated for 15 min at 27°C in a total volume of 250 µl of pH 6.8 50 mM bis-tris propane

buffer, 1 mM DTT, 10% v/v glycerol, in the presence of 3-hydroxypicolinic acid<sup>-</sup> (1 mM), ATP (2 mM), MgCl<sub>2</sub> (5 mM) and tetrasodium pyrophosphate labelled with the radioactive isotope 32 of the phosphorus atom (200 μM).

5           The reaction is stopped by adding 1 ml of a suspension of activated charcoal at a concentration of 10 g/l in a mixture of 75% of 0.1 M tetrasodium pyrophosphate and 25% of 14% perchloric acid. After stirring, the charcoal is collected and washed with  
10 twice 1 ml of the pyrophosphate/perchloric acid mixture. The radioactive organic molecules are then eluted with three times 1 ml of a mixture of 50% of methanol and 50% of N ammonia solution into a counting vial containing 12 ml of water. The radioactivity is  
15 measured by the Cerenkov effect with a scintillation counter (PACKARD Minaxi TriCarb 4000).

          The unit of enzymatic activity is defined as the amount of enzyme needed to incorporate 1 μmol of pyrophosphate into ATP in the course of 1 hour under  
20 the conditions described above.

#### 5.2.1.B. Purification of S. pristinaespiralis SP92 3-hydroxypicolinic acid:AMP ligase

          This experiment illustrates how an enzyme of S. pristinaespiralis SP92 participating in the  
25 biosynthesis pathway of pristinamycin IA may be purified.

          Using the assay described above in Example 5.2.1.A, the purification of 3-hydroxypicolinic

acid:AMP ligase is carried out as described below, taking care to freeze the active fractions at  $-70^{\circ}\text{C}$  and store them at  $-30^{\circ}\text{C}$  between successive steps if necessary.

5                   234 g of a centrifugation pellet, washed with 0.1 M phosphate buffer pH 7.2 containing 10% v/v of glycerol, of an S. pristinaespiralis SP92 culture harvested at the beginning of the pristinamycin production phase are taken up with 234 ml of pH 8.0  
10 100 mM Tris-HCl buffer containing 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 15% v/v glycerol and 0.6 mg/ml of lysozyme. The suspension thereby obtained is incubated for 30 minutes at  $27^{\circ}\text{C}$  and then centrifuged at 50,000 g for 1 hour. The crude extract thereby  
15 collected is injected in pH 8.0 100 mM Tris-HCl buffer, 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 15% v/v glycerol onto a column (80 ml) of Q Sepharose Fast Flow. The proteins are eluted with a linear KCl gradient (0 to 0.4 M). The fractions containing the enzymatic activity  
20 (detected by means of the test described in Example 5.2.1.A) are pooled and diluted with one volume of pH 8.0 100 mM Tris-HCl buffer, 1 mM benzamidine, 1 mM PMSF, ~~15%~~ v/v glycerol containing 2 M ammonium sulphate. The proteins are then chromatographed on a  
25 column (50 ml) of Phenyl Sepharose with a decreasing ammonium sulphate gradient (1.0 M to 0 M) in pH 8.0 100 mM Tris-HCl buffer, 1 mM benzamidine, 1 mM PMSF, 15% v/v glycerol. After the addition of 4 mM DTE, the

active fractions are pooled, concentrated to 5 ml on Centriprep 10 and then applied to a column (100 ml) of Superose 12 prep grade. The fractions containing the desired activity are pooled and injected in pH 8.0

5 100 mM Tris-HCl buffer, 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 15% v/v glycerol (approximately 6 mg per injection) onto a column of MonoQ HR 5/5 eluted with a linear KCl gradient (0 to 0.4 M). The active fractions are pooled, concentrated to 1 ml on Centricon 10,  
10 diluted with 3 volumes of pH 6.8 50 mM bis-tris propane buffer, 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 15% v/v glycerol, and then injected (2 mg per injection) in the latter buffer onto a column of MonoQ HR 5/5 eluted with a linear KCl gradient (0 to 0.3 M). The best fractions  
15 containing the desired ligase are pooled and then applied in pH 6.8 20 mM sodium phosphate buffer, 50 mM sodium sulphate to a Bio-Sil SEC 250 column. The activity peak is detected in this technique at a molecular weight centred at 60,000.

20 The protein possessing the activity of activation of 3-hydroxypicolinic acid is hereinafter designated SnbA.

After this step, the enzyme is pure and, in SDS-PAGE electrophoresis, its molecular weight is  
25 estimated at approximately 67,000.

Table: Purification of 3-hydroxypicolinic  
acid:AMP ligase

Purification step	Vol. (ml)	Protein (mg)	Sp.Act. $\mu\text{mol/h/mg}^a$	Yield (%)	Purification factor
Crude extract	246	2050	(0.06)		
Q Sepharose	40	188	0.47	100	1
Phenyl Sepharose	70	35	2.21	88	4.7
Superose 12	16	17	2.03	39	4.3
MonoQ pH 8.0	4.5	9.0	2.09	21	4.5
MonoQ pH 6.8	1.0	2.0	2.9	6.6	6.2
Bio-sil 250	2.5	0.23	12.4	3.2	26

\* The activity in the crude extract cannot be measured accurately owing to exchanges between pyrophosphate and ATP which are not specific to 3-hydroxypicolinic acid.

The purification factor is calculated from the increase in specific activity of the fractions during the purification.

5.2.2. Production of oligonucleotides from the protein sequence:

This example describes how, starting from the  $\text{NH}_2$ -terminal and internal sequences of the protein 3-hydroxypicolinic:AMP ligase, it is possible to synthesize oligonucleotides.

The  $\text{NH}_2$ -terminal sequence of the protein SnbA was deduced by microsequencing as described in Example

5.1.2. About twenty residues were identified in this way.

A sequence of approximately 20 amino acids internal to the protein SnbA was also identified after  
5 trypsin hydrolysis and purification of the fragments obtained on a Vydac C18 HPLC column.

5.2.3. Labelling of the mixtures of synthetic oligonucleotides and hybridization of the genomic DNA libraries of S. pristinaespiralis SP92.

10 This example describes how oligonucleotides specific for a gene for the biosynthesis of pristinamycins may be radioactively labelled and then hybridized with membranes onto which DNA of genomic libraries of S. pristinaespiralis has been transferred.

15 Labelling the oligonucleotides is carried out by transfer at the 5'-terminal position of the [ $\gamma$ - $^{32}$ P]phosphate group of ATP with T4 polynucleotide kinase, as described in Example 5.1.3.

20 Approximately 2 x 500 ng of each mixture of oligonucleotides were labelled in this way with  $^{32}$ P and were used to hybridize each of the two libraries.

Hybridization of the membranes of each library was carried out as described in Example 5.1.3.

25 5.2.4. Isolation of cosmid pIBV2 and determination of the region containing the structural gene for 3-hydroxypicolinic acid:AMP ligase

This example illustrates how it is possible to obtain a cosmid as constructed in Example 3

containing at least the structural gene for 3-hydroxy-picolinic acid:AMP ligase.

Cosmid pIBV2 was isolated from a clone of the library produced in E. coli strain DH1 which hybridized  
5 with both mixtures of oligonucleotides simultaneously.

This cosmid was purified as described in Example 2. It contains a genomic DNA insert of S. pristinaespiralis SP92 whose size was estimated at 47 kb. A map (Figure 5) was established from digestions  
10 with different restriction enzymes, as described in Example 5.1.4.

Southern hybridizations of pIBV2 DNA, digested by means of different enzymes, with the mixtures of oligonucleotides enabled the region  
15 containing the structural gene for 3-hydroxypicolinic acid:AMP ligase to be identified. Southern blotting and hybridizations were carried out as described in Example 5.1.4.

The hybridization results enabled it to be  
20 shown that cosmid pIBV2 possessed a 5.5-kb EcoRI-BglII fragment containing the sequence homologous to the probes synthesized in Example 5.2.2.

5.3. Demonstration of the presence of a portion of the structural gene for pristinamycin I synthase II (SnbC) on cosmid pIBV3  
25

This example illustrates how it is possible to identify the presence of genes for the biosynthesis of pristinamycins I on a cosmid which has already been

isolated (Example 5.1).

5.3.1. Identification of pristinamycin I synthase II involved in the incorporation of threonine and aminobutyric acid residues into the peptide chain pristinamycin IA

This example illustrates how the protein responsible for the incorporation of threonine and aminobutyric acid residues into the peptide chain of pristinamycin IA may be purified to homogeneity from S. pristinaespiralis SP92.

5.3.1.A. Assay of the partial activities of pristinamycin I synthase II

This example illustrates the assay of activities of the biosynthesis pathway of pristinamycin IA which have never before been described and which possess the noteworthy property of being expressed only during the period of production of pristinamycins. The activities in question are the partial activities of the peptide synthase responsible for the incorporation of threonine and aminobutyric acid residues into the peptide chain of pristinamycin IA (Figure 10) in the presence of ATP and  $MgCl_2$ .

The threonine:AMP ligase and aminobutyric acid:AMP ligase activities are measured in an enzymatic test of ATP-pyrophosphate exchange similar to that described in 5.2.1.A for 3-hydroxypicolinic acid:AMP ligase.

The aminoacylation reactions of the enzyme

with threonine or alanine (an analogue of aminobutyric acid which is found in pristinamycin IC) enable the peptide synthase to be differentiated from other enzymes which may effect an ATP-pyrophosphate exchange, and in particular aminoacyl-tRNA synthetases. The test of aminoacylation of the enzyme with tritium-labelled threonine described below is hence the one which was used in this example.

The enzyme fractions to be assayed (0.2 to 2 units) are incubated for 15 min at 27°C in a total volume of 250 µl of pH 6.8 50 mM bis-tris propane buffer, 1 mM DTT, 10% v/v glycerol in the presence of 1 µCi of [3-<sup>3</sup>H]-L-threonine (15 Ci/mmol), ATP (2 mM) and MgCl<sub>2</sub> (5 mM).

The reaction is stopped by adding 150 µl of 25% trichloroacetic acid solution. The precipitated proteins are collected on a microfilter and washed with 3 times 400 µl of 7% trichloroacetic acid, before being eluted with twice 400 µl of N sodium hydroxide into a counting vial containing 1 ml of N HCl and 12 ml of scintillation cocktail (Beckmann Readygel). The amount of radioactivity contained in this vial is measured with a scintillation counter (PACKARD Minaxi TriCarb 4000). It represents the amount of threonine bound covalently to the desired peptide synthase.

The unit of enzymatic activity is defined as the amount of enzyme needed to bind 1 picomole of threonine covalently in 15 min under the conditions

described above.

#### 5.3.1.B. Purification of pristinamycin I synthase II

This experiment illustrates how an enzyme of  
5 S. pristinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IA may be purified.

Using the acid described above in Example  
5.3.1.A., purification of the peptide synthase  
10 responsible for the incorporation of threonine and aminobutyric acid residues into the peptide chain of pristinamycin IA is carried out as described below, taking care to work at 4°C and to store the active fractions at -70°C.

15 150 g of a centrifugation pellet, washed with 0.1 M phosphate buffer pH 7.2 containing 10% v/v of glycerol, of an S. pristinaespiralis SP92 culture harvested at the beginning of the pristinamycin production phase are taken up with 450 ml of pH 8.0  
20 100 mM Tris-HCl buffer containing 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 1 mM EDTA, 1 mM EGTA, 15% v/v glycerol. The suspension thereby obtained is ground using a French Press adjusted to a pressure of 5000 psi, and then centrifuged at 50,000 g for 1 hour.

25 The crude extract thereby collected is injected in pH 8 100 mM Tris-HCl buffer, 4 mM DTE, 2 mM benzamidine, 2 mg/l leupeptin, 1 mg/l E-64, 15% v/v glycerol onto a column (200 ml) of Q Sepharose Fast Flow. The proteins

are eluted with a linear KCl gradient (0 to 0.6 M). At outflow from the column, each fraction is treated with one-tenth of its volume of a solution of 1 mM PMSF, 5 mM EDTA, 5 mM EGTA. The fractions containing the enzymatic activity (detected by means of the test described in Example 5.3.1.A) are pooled and reconcentrated by ultrafiltration on Centriprep 30 to a final volume of 28 ml. This concentrate is injected in 4-ml aliquots onto a Superdex 200 Hi-Load 16/60 permeation column equilibrated in pH 6.8 50 mM bis-tris propane buffer, 1 mM benzamidine, 4 mM DTE, 0.2 mM Pefabloc, 1 mM EDTA, 0.1 M KCl, 20% v/v glycerol. After assaying, the active fractions are pooled and reconcentrated to 15 ml on Centriprep 30, then desalted on PD-10 in pH 8.0 100 mM Tris-HCl buffer, 4 mM DTE, 2 mM benzamidine, 2 mg/l leupeptin, 1 mg/l E-64, 20% v/v glycerol and applied in two portions to a MonoQ HR 10/10 column equilibrated and eluted with a linear gradient of from 0.4 M KCl in this same buffer. The fractions containing the desired activity are pooled, reconcentrated on Centriprep 30 and then Centricon 30 to a final volume of 1 ml and injected in five portions onto a column of Superose 6 HR 10/30 in pH 6.8 50 mM bis-tris propane buffer, 1 mM benzamidine, 4 mM DTE, 0.2 mM Pefabloc, 1 mM EDTA, 0.1 M KCl, 20% v/v glycerol. The activity peak is detected in this technique at a molecular weight centred at 450,000.

After this step the enzyme is pure and, in

SDS-PAGE electrophoresis, its molecular weight is estimated at approximately 240,000. This band also contains all radioactivity of the protein labelled by aminoacylation with tritiated threonine.

5           At this stage, the maximal activity of the enzyme using a concentration of 100  $\mu\text{Ci/ml}$  of threonine (15  $\text{Ci/mmol}$ ) amounts to 3670 units/mg; the enzyme is also capable of forming adenylates with L-aminobutyric acid or L-alanine; an aminoacylation reaction of the  
10 enzyme with tritiated alanine is detected, and the maximal activity in the presence of 200  $\mu\text{Ci/ml}$  of [2,3- $^3\text{H}$ ]-L-alanine (15  $\text{Ci/mmol}$ ) is 2290 pmol/mg in 15 min.

Table: Purification of pristinamycin I synthase II

Purification step	Vol. (ml)	Protein (mg)	Sp.Act. <sup>a</sup> (units/mg)	Yield (%)	Purification factor
Crude extract	445	4700	(1)	-	-

Superose 6	7.5	2.8	122	6	17

a: The activity in the crude extract cannot be measured accurately.

The purification factor is calculated from  
25 the increase in specific activity of the fractions

during the purification.

### 5.3.2. Production of oligonucleotides from the protein sequence

This example describes how, starting from internal sequences of pristinamycin I synthase II, it is possible to synthesize oligonucleotides.

The internal sequences of the peptide synthase which is responsible for the incorporation of threonine and aminobutyric acid residues into the peptide chain of pristinamycin IA were deduced by microsequencing as described in Example 5.1.2. after trypsin hydrolysis and purification of the fragments obtained on a Vydac C18 column.

5.3.3. Labelling of the mixtures of synthetic oligonucleotides and Southern hybridization of cosmid

15 PIBV3 DNA

This example describes how oligonucleotides specific for a gene for the biosynthesis of pristinamycins I may be radioactively labelled and then hybridized with a membrane onto which cosmid PIBV3 DNA has been transferred.

20 Labelling of the oligonucleotides is carried out by transfer at the 5'-terminal position of the [ $\gamma$ - $^{32}\text{P}$ ]phosphate group of ATP with T4 polynucleotide kinase, as described in 5.1.3.

25 Approximately 500 ng of the mixture of oligonucleotides were labelled in this way with  $^{32}\text{P}$ , and were used for Southern hybridization of PIBV3 DNA digested with different enzymes. These hybridizations

enabled it to be shown that a portion of the structural gene for pristinamycin I synthase II was carried by cosmid pIBV3, and enabled the region containing this gene to be identified. Southern blotting and  
5 hybridization were carried out as described in Example 5.1.4.

The hybridization results enabled it to be shown that cosmid pIBV3 possessed a 6.2-kb SphI fragment containing the sequence homologous to the  
10 probes synthesized in Example 5.3.2.

5.4. Demonstration of the presence of a portion of the structural gene for pristinamycin I synthase III (SnbD) on cosmid pIBV3

This example illustrates how it is possible  
15 to identify the presence of genes for the biosynthesis of pristinamycins I on a cosmid which has already been isolated (Example 5.1).

5.4.1. Identification of pristinamycin I synthase III involved in the incorporation of proline  
20 and p-dimethylaminophenylalanine residues into the peptide chain of pristinamycin IA

This example illustrates how the protein responsible for the incorporation of proline and p-dimethylaminophenylalanine-residues into the peptide  
25 chain of pristinamycin IA may be purified to homogeneity from S. pristinaespiralis SP92.

5.4.1.A. Assay of partial activities of pristinamycin I synthase III

This example illustrates the assay of activities of the biosynthesis pathway of pristinamycin IA which have never before been described and which possess the noteworthy property of being expressed only during the period of production of pristinamycins. The activities in question are partial activities of the peptide synthase responsible for the incorporation of proline and para-dimethylaminophenylalanine residues into the peptide chain of pristinamycin IA (Figure 11) in the presence of SAM, ATP and  $MgCl_2$ .

The proline:AMP ligase and p-dimethylamino-phenylalanine:AMP ligase activities are measured in an enzymatic test of ATP-pyrophosphate exchange similar to that described in 5.2.1.A. for 3-hydroxypicolinic acid:AMP ligase.

The aminoacylation reactions of the enzyme with proline and p-dimethylaminophenylalanine make it possible to differentiate the peptide synthase from other enzymes which may perform a ATP-pyrophosphate exchange, and in particular aminoacyl-tRNA synthases. The same applies to the N-methylation of the  $\alpha$ -amino function of p-dimethylaminophenylalanine acylated on the enzyme. The latter test characteristic of N-methylation is hence the one which was used in this example.

The enzyme fractions to be assayed (0.2 to 2 units) are incubated for 15 min at 27°C in a total volume of 250  $\mu$ l of pH 6.8 50 mM bis-tris propane

buffer, 1 mM DTT, 10% v/v glycerol in the presence of 1  $\mu$ Ci of [methyl- $^3$ H]-SAM (15 Ci/mmol), para-dimethylamino-L-phenylalanine (1 mM), ATP (2 mM) and MgCl<sub>2</sub> (5 mM).

5           The reaction is stopped by adding 150  $\mu$ l of 25% trichloroacetic acid solution. The precipitated proteins are collected on a microfilter and washed with 3 times 400  $\mu$ l of 7% trichloroacetic acid, before being eluted with twice 400  $\mu$ l of N sodium hydroxide into a  
10   counting vial containing 1 ml N HCl and 12 ml of scintillation cocktail (Beckmann Readygel). The amount of radioactivity contained in this vial is measured with a scintillation counter (PACKARD Minaxi TriCarb 4000). It represents the amount of N-methylated para-  
15   dimethylaminophenylalanine bound covalently to the desired peptide synthase.

          The unit of enzymatic activity is defined as the amount of enzyme needed to bind 1 picomole of N-methylated p-dimethylaminophenylalanine covalently in  
20   15 min under the conditions described above.

#### 5.4.1.B. Purification of pristinamycin I synthase III

          This experiment illustrates how an enzyme of S. pristinaespiralis SP92 participating in the  
25   biosynthesis pathway of pristinamycin IA may be purified.

          Using the assay described above in Example 5.4.1.A, purification of the peptide synthase

responsible for the incorporation of proline and para-dimethylaminophenylalanine residues into the peptide chain of pristinamycin IA is carried out as described below, taking care to work at 4°C and to store the  
5 active fractions at -70°C.

250 g of a centrifugation pellet, washed with 0.1 M phosphate buffer pH 7.2, 1 mM PMSF, 5 mM EDTA, 5 mM EGTA, 0.5 M KCl, 10% v/v glycerol, of an S. pristinaespiralis SP92 culture harvested at the  
10 beginning of the pristinamycin production phase are taken up with 750 ml of pH 8.0 100 mM Tris-HCl buffer containing 4 mM DTE, 5 mM benzamidine, 0.2 mM Pefabloc, 1 mM EDTA, 1 mM EGTA, 2 mg/l leupeptin, 2 mg/l STI, 2 mg/l aprotinin, 1 mg/l E-64, 20% v/v glycerol. The  
15 suspension thereby obtained is ground using a French Press adjusted to a pressure of 5000 psi, and then centrifuged at 50,000 g for 1 h. The crude extract thereby collected is fractionated by ammonium sulphate precipitation. The protein fraction coming out at  
20 between 0 and 35% ammonium sulphate saturation is redissolved in the disruption buffer and desalted on a column of Sephadex G 25 Fine equilibrated and eluted in this same buffer. The proteins thus prepared are injected in pH 8.0 100 mM Tris-HCl buffer, 4 mM DTE,  
25 2 mM benzamidine, 2 mg/l leupeptin, 1 mg/l E-64, 20% v/v glycerol onto a column (200 ml) of Q Sepharose Fast Flow, and are then eluted with a linear KCl gradient (0 to 0.6 M). At outflow from the column, each fraction is

treated with one-tenth of its volume of a solution of 2 mM Pefabloc, 5 mM EDTA, 5 mM EGTA, 5 mM benzamidine. The fractions containing the enzymatic activity (detected by means of the test described in Example 5.4.1.A) are pooled and precipitated with ammonium sulphate at 80% saturation. The proteins which have come out are redissolved in pH 6.8 50 mM bis-tris propane buffer, 1 mM benzamidine, 1 mM DTE, 0.2 mM Pefabloc, 1 mM EDTA, 1 mM EGTA, 2 mg/l leupeptin, 0.15 M NaCl, 20% v/v glycerol, and injected in 5 4-ml aliquot portions onto a Superdex 200 Hi-Load 16/60 permeation column equilibrated and eluted in this same buffer. After assay, the active fractions are pooled and reconcentrated to 3 ml on Centriprep 30, then rediluted to 20 ml with pH 8.0 100 mM Tris-HCl buffer, 4 mM DTE, 1 mM benzamidine, 1 mM PMSF, 20% v/v glycerol and applied in two portions to a MonoQ HR 10/10 column equilibrated and eluted with a linear gradient from 0.4 M KCl in this same buffer. The best fractions containing the desired activity are pooled and used as material for characterization of the activities of the enzyme and for its microsequencing.

After this step, the enzyme is pure and, in SDS-PAGE electrophoresis, its molecular weight is estimated at approximately 250,000. This band also contains all the radioactivity of the protein labelled by aminoacylation with tritiated SAM and para-dimethylaminophenylalanine. In permeation on Superose

6 HR 10/30, the native molecular weight of the enzyme is estimated at 700,000.

At this stage, the enzyme is also capable of forming adenylates with proline; an aminoacylation  
 5 reaction of the enzyme with tritiated proline is detected, and the maximal activity in the presence of 200  $\mu$ Ci/ml of [5- $^3$ H]-L-proline (34 Ci/mmol) is 2490 pmol/mg in 15 min.

Table: Purification of pristinamycin I synthase III

25                    5.4.3. Labelling of the mixtures of synthetic  
oligonucleotides and Southern hybridization of cosmid  
pIBV3 DNA

This example describes how oligonucleotides

specific for a gene for the biosynthesis of pristinamycins I may be radioactively labelled and then hybridized with a membrane onto which cosmid pIBV3 DNA has been transferred.

5            Labelling of the oligonucleotides is carried out by transfer at the 5'-terminal position of the [ $\gamma$ - $^{32}$ P]phosphate group of ATP with T4 polynucleotide kinase, as described in 5.1.3.

10           Approximately 500 ng of the mixture of oligonucleotides were labelled in this way with  $^{32}$ P, and were used for Southern hybridization of pIBV3 DNA digested with different enzymes. These hybridizations enabled it to be shown that a portion of the structural gene for pristinamycin I synthase III was carried by  
15           cosmid pIBV3, and enabled the region containing this gene to be identified. Southern blotting and hybridization were carried out as described in Example 5.1.4.

20           The hybridization results enabled it to be shown that cosmid pIBV3 possessed an 8.4-kb SphI fragment containing the sequence homologous to the probes synthesized in Example 5.4.2.

25           5.5. Demonstration of the presence of a portion of the structural gene for pristinamycin I synthase IV (SnbE) on cosmid pIBV3

            This example illustrates how it is possible to identify the presence of genes for the biosynthesis of pristinamycins I on a cosmid which has already been

isolated (Example 5.1).

5.5.1. Identification of the peptide synthase (referred to as pristinamycin I synthase IV) responsible for the incorporation of the phenylglycine residue into the peptide chain of pristinamycin IA

5.5.1.A. Assay of enzymatic activities carried by the peptide synthase (pristinamycin I synthase IV) responsible for the incorporation of the phenylglycine residue into the peptide chain of pristinamycin IA

This example illustrates the assay of an enzymatic activity of the biosynthesis pathway of pristinamycin IA which has not been described hitherto and which possesses the noteworthy property of being expressed only during the period of production of pristinamycins in the wild-type microorganism. The activity in question is that of the peptide synthase (pristinamycin I synthase IV) responsible for the incorporation of the L-phenylglycine residue into the peptide chain (Figure 12) in the presence of ATP and MgCl<sub>2</sub>. The phenylglycine:AMP ligase activity of pristinamycin I synthase IV is measured in an enzymatic test of ATP-pyrophosphate exchange similar to that described in 5.2.1.A. for 3-hydroxypicolinic acid:AMP ligase activity, in the presence of L-phenylglycine (1 mM) and KCl (50 mM) in the incubation buffer.

5.5.1.B. Purification of the peptide synthase responsible for the incorporation of the phenylglycine

residue (pristinamycin I synthase IV) into the peptide chain of pristinamycin IA

This example illustrates how an enzyme of S. pristinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IA may be purified. Using the assay described above in Example 5.5.1.A. The purification of pristinamycin I synthase IV is carried out as described below. All the operations are performed at 4°C. The fractions containing the activity are frozen immediately and stored at -70°C.

70 g of wet cells, harvested as described in Example 5.2.1.B., are resuspended in 250 ml of cell lysis buffer (100 mM Tris-HCl pH 8.0 containing 25% of glycerol, 4 mM DTE, 1 mM EGTA, 1 mM EDTA, 1 mM PMSF, 1 mg/l E-64, 2 mg/l STI, 2 mg/l  $\alpha_2$ -macroglobulin, 1 mg/l leupeptin, 2 mg/l aprotinin, 5 mM benzamidine, 0.6 mg/ml lysozyme. The solution thereby obtained is kept stirring at 4°C for 1 h and then centrifuged at 50,000 g for 1 h. The supernatant is then injected in the cell lysis buffer onto a column of Sephadex G-25, and the excluded fraction (approximately 250 mg of protein, injected in each chromatographic run) is injected onto a column of Mono Q HR 16/10 (Pharmacia) equilibrated with 100 mM Tris-HCl buffer pH 8.0, 4 mM DTE, 1 mM EGTA, 1 mM EDTA, 1 mg/l E-64, 2 mg/l STI, 20% glycerol. The proteins are eluted with a linear gradient of from 0 to 0.6 M KCl and, at outflow from

the column, each fraction is treated with one-tenth of its volume of a solution of 2 mM Pefabloc, 5 mM EGTA, 5 mM EDTA. The fractions containing the activity are pooled and then mixed with 1 volume of 100 mM Tris-HCl

5 pH 8.0, 15% glycerol, 1 mM PMSF, 1 mM benzamidine, 4 mM DTT, 3.4 M ammonium sulphate per 3 volumes of fraction. The solution is injected onto a column of Phenyl Superose HR 10/10 (one-fifth of the solution is injected at each chromatographic run), and the proteins

10 are eluted with a decreasing linear gradient of from 0.9 to 0 M ammonium sulphate. The fractions containing the activity are pooled. The solution is concentrated to 3500  $\mu$ l in a Centriprep 30 and injected in two portions onto a Superdex 200 Hi-Load 16/60 column

15 equilibrated and eluted with 50 mM bis-tris propane buffer pH 6.8 containing 20% of glycerol, 0.15 M NaCl, 4 mM DTT, 1 mM PMSF, 1 mM benzamidine, 1 mM EDTA. The active fraction is diluted with 9 volumes of 50 mM bis-tris propane buffer pH 6.8 containing 25% of

20 glycerol, 4 mM DTT, 1 mM PMSF, 1 mM benzamidine, and then injected onto a column of Mono Q HR 5/5 equilibrated in the same buffer. The desired activity is eluted with a linear gradient of from 0 to 0.4 M KCl and concentrated to 630  $\mu$ l in a Centricon-30. The

25 desired protein is then purified by electrophoresis on 6% polyacrylamide gel after denaturation of the sample by heating for 10 min at 80°C with an SDS/mercapto-ethanol mixture. After electrophoresis and staining of

the gel with Coomassie blue, the gel band containing the protein is cut out and the protein is electroeluted from the gel in a Centrilutor.

Note: the band corresponding to pristinamycin I synthase IV is identified by comparison with a tritiated (by covalent binding to tritiated phenylglycine; see description in Example 5.5.2.) pristinamycin I synthase IV standard.

After this step, the enzyme is pure in electrophoresis (SDS-PAGE). Its molecular weight is estimated at approximately 170,000.

#### 5.5.2. Labelling of pristinamycin I synthase IV by thioesterification of radioactive phenylglycine on the enzyme

After activation in the form of an adenylate through phenylglycine:AMP ligase activity, phenylglycine is transferred to a thiol group of the active site of the enzyme before being incorporated into the peptide chain during elongation (general process of biosynthesis of peptide antibiotics known by the name of "thiotemplate mechanism"). Generally speaking, radioactive labelling of the protein effecting the activation of amino acid may hence be performed by preparing the thioester derivative with a radioactive form of the amino acid.

As an example, the radioactive labelling of pristinamycin I synthase IV is accomplished by incubating 50 µg of the protein (active fraction

emerging from the Mono Q HR 5/5 chromatography column; see above in Example 5.5.1.B.) for 1 hour at 27°C with 100 µCi of (RS)-2-phenyl[2-<sup>3</sup>H]glycine (18 Ci/mmol; Amersham) in 70 µl of 50 mM bis-tris propane buffer pH 6.8 containing 20% of glycerol, 25 mM MgCl<sub>2</sub>, 5 mM ATP, 0.15 M NaCl, 4 mM DTT, 1 mM PMSF, 1 mM benzamidine, 1 mM EDTA. After denaturation (SDS alone without mercaptoethanol), the proteins are separated by electrophoresis (SDS-PAGE, 6% gel) and visualized with Coomassie blue. Analysis of the radioactivity profile by counting the protein bands as well as by autoradiography (Hyperfilm MP; fluorography after impregnation of the gel with Amersham Amplify) discloses a single radioactive band with a molecular weight of 170,000.

Table: Purification of pristinamycin I synthase IV

Purification Step	Protein (mg)	Sp.Act. (cpm/mg) <sup>a</sup>	Protein (mg)	Purification factor
Crude extract	2200	3.6	-	-
Mono Q 16/10	136	58	100	16
Phenyl Superose	32.6	175	72	49
Superdex 200	3.1	870	34	240
Mono Q 5/5	2.0	1000	25	280
Electroelution SDS-PAGE	0.1	-	-	-

The specific activity cannot be measured accurately in the crude extract owing to the high level of non-phenylglycine-dependent ATP-pyrophosphate exchange. The specific activity value was calculated from the number of units present at emergence from the first chromatographic step expressed with reference to the amount of protein in the crude extract.

#### 5.5.3. Other activities carried by pristinamycin I synthase IV

Purification of the peptide synthase responsible for the incorporation of phenylglycine, described in Example 5.5.2., led to a pure protein of molecular weight 170,000. This protein does not activate the other amino acids tested, especially pipecolic acid or 4-oxopipecolic acid. A second preparation of this protein, performed under the conditions described in 5.5.1.B. eliminating, however, the Phenyl Superose step, starting from another culture of S. pristinaespiralis SP92, the crude extract of which was prepared in a French Press as described in 5.4.1B, led to a protein which, at emergence from the Mono Q HR 5/5 step, was equivalent in purity to that obtained at the same step in the example described in 5.5.1.B., but possessed a molecular weight of approximately 250,000 in SDS-PAGE. This new preparation was competent for the activation and thioesterification of phenylglycine, but possessed, in addition, an ATP-pyrophosphate exchange activity with L-pipecolic acid

(1 mM) in the exchange test similar to that described in 5.2.1.A. for 3-hydroxypicolinic acid. Moreover, it could be shown that the 170,000 protein does not possess ATP-pyrophosphate exchange activity with L-pipecolic acid even in preparations of the protein that are still very impure. It should be noted that S. pristinaespiralis SP92 naturally produces small amounts of a pristinamycin IA analogue having a pipecolic acid residue in place of 4-oxopipecolic acid. Hence this demonstrates that the peptide synthase responsible for the incorporation of phenylglycine (pristinamycin I synthase IV) also catalyses the incorporation of the preceding residue (probably pipecolic acid). The difference in molecular weight obtained for pristinamycin I synthase IV in the two preparations (170,000 and 250,000) is attributed to a phenomenon of partial proteolytic cleavage in the first case, leading to loss of the activity of activation of L-pipecolic acid.

#### 5.5.4. Synthesis of oligonucleotides from the protein sequence

This example describes how, starting from an internal sequence of pristinamycin I synthase IV, it is possible to set about testing for the corresponding gene using suitably chosen oligonucleotides.

An internal sequence of pristinamycin I synthase IV of 15 amino acids was identified after cyanogen bromide cleavage of the purified protein and

purification of the fragments obtained on a Vydac C18 HPLC column.

5.5.5. Labelling of the mixtures of synthetic oligonucleotides and Southern hybridization of cosmid pIBV3 DNA

This example describes how oligonucleotides specific for a gene for the biosynthesis of pristinamycins I may be radioactively labelled and then hybridized with a membrane onto which cosmid pIBV3 DNA has been transferred.

Labelling of the oligonucleotides is carried out by transfer at the 5'-terminal position of the

[ $\gamma$ - $^{32}\text{P}$ ]phosphate group of ATP with T4 polynucleotide kinase, as described in 5.1.3.

Approximately 500 ng of the mixture of oligonucleotides were labelled in this way with  $^{32}\text{P}$ , and were used for Southern hybridization of pIBV3 DNA digested with different enzymes. These hybridizations enabled it to be shown that a portion of the structural gene for pristinamycin I synthase II was carried by cosmid pIBV3, and enabled the region containing this gene to be identified. Southern blotting and hybridization were carried out as described in Example 5.1.4.

The hybridization results enabled it to be shown that cosmid pIBV3 possessed a 6.6-kb SphI fragment containing the sequence homologous to the probes synthesized in Example 5.5.4.

#### 5.6. Isolation of cosmid pIBV4 containing the structural gene for FMN reductase (snaC)

This example illustrates how it is possible to obtain a cosmid as constructed in Example 3 containing at least one gene for the biosynthesis of PII.

##### 5.6.1. Identification of FMN reductase associated with pristinamycin IIA synthase

This example illustrates how the protein responsible for reduction of FMN by NADH to form the FMNH<sub>2</sub>, needed for the reaction catalysed by pristinamycin IIA synthase may be purified to homogeneity from

S. pristinaespiralis SP92.

5.6.1.A. Assay of FMN reductase activity

This example illustrates the assay of an activity of the biosynthesis pathway of pristinamycin IIA which has never before been described and which possesses the noteworthy property of being expressed only during the period of production of pristinamycins. The enzyme in question is FMN reductase, also referred to as NADH:FMN oxidoreductase, which catalyses the reduction of FMN to FMNH<sub>2</sub> (Figure 13) in the presence of NADH. FMN reductases catalysing the same reaction which are specific or otherwise for NADH or NADPH and associated with other biosynthesis pathways have been described elsewhere (Duane et al., 1975, Jablonski et al., 1977, Watanabe et al., 1982).

Two assays are used to detect this activity:

The first is based on a coupling with the pristinamycin IIA synthase described in Example 5.1.1., and is used for the first steps of the purification. The enzyme fractions to be assayed (0.002 to 0.005 units) are incubated for 1 hour at 27°C in a total volume of 500 µl of 50 mM bis-tris propane buffer pH 6.8 containing NADH (500 µM), FMN (2 µM), pristinamycin IIB (20 µM) and 0.01 units of pristinamycin IIA synthase described in Example 5.1.1. The pristinamycin IIA formed is assayed by HPLC as described in Example 5.1.1.A.

The unit of enzymatic activity is defined as

the amount of enzyme needed to synthesize 1  $\mu\text{mol}$  of pristinamycin IIA per minute under the conditions described above.

5       The second assay is a spectrophotometric assay, and can be employed only with at least partially purified fractions. The enzyme fractions to be assayed (0.006 to 0.030 units) are incubated for 13 min at 27°C in a total volume of 3 ml of 50 mM bis-tris propane buffer pH 6.8 containing NADH (500  $\mu\text{M}$ ) and FMN (2  $\mu\text{M}$ ).  
10      After 7 min of incubation, 6 readings of the optical density at 340 nm taken at 1-min intervals are performed against a reference curve without enzyme. The activity in  $\mu\text{mol}/\text{min}$  is calculated by dividing the slope of decrease per min in the optical density by a  
15      factor of 6.2 (optical density of 1 mol of NADH at 340 nm).

The unit of enzymatic activity is defined as the amount of enzyme needed to consume 1  $\mu\text{mol}$  of NADH per minute under the conditions described above.

20       5.6.1.B. Purification of S. pristinaespiralis SP92 FMN reductase

This experiment illustrates how an enzyme of S. pristinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IIA may be  
25      purified.

Using the assays described above in Example 5.6.1.A., the purification of FMN reductase is carried out as described below, taking care to freeze and store

the active fractions at  $-30^{\circ}\text{C}$  between successive steps if necessary.

500 g of a centrifugation pellet, washed with 0.1 M phosphate buffer pH 7.2 containing 10% v/v of glycerol, of an S. pristinaespiralis SP92 culture harvested at the beginning of the pristinamycin production phase are taken up with 1500 ml of 50 mM bis-tris propane buffer pH 6.8 containing 5 mM DTT, 10% v/v of glycerol and 0.2 mg/ml of lysozyme. The suspension thereby obtained is incubated for 45 min at  $27^{\circ}\text{C}$  and then centrifuged at 50,000 g for 1 hour. The crude extract thereby collected is fractionated by ammonium sulphate precipitation. The protein fraction precipitating at between 40 and 75% saturation is desalted on a column of Sephadex G-25 Fine and then injected in pH 6.8 50 mM bis-tris propane buffer, 5 mM DTT, 10% v/v glycerol onto a column (300 ml) of Q Sepharose Fast Flow. The active proteins are not retained on the column, and they are desalted on a column of Sephadex G-25 Fine and then reinjected in pH 8.2 50 mM Tris-HCl buffer, 5 mM DTT, 10% v/v glycerol onto a column (35 ml) of Q Sepharose Fast Flow and eluted with a linear KCl gradient (0 to 0.5 M). The fractions containing the enzymatic activity (detected by means of the first test described in Example 5.6.1.A) are pooled, desalted on a column of Sephadex G-25 Fine and then injected in pH 8.2 50 mM Tris-HCl buffer, 5 mM DTT, 10% v/v glycerol onto a MonoQ HR

10/10 column. The proteins retained are eluted directly by the same buffer to which 0.2 M KCl has been added. They are collected in a volume of 1 ml, which is immediately reinjected onto a column of Superdex 75 HR 10/30 eluted with pH 6.8 50 mM bis-tris propane buffer, 1 mM DTT, 10% v/v glycerol. The fractions containing the desired activity (detected from this step onwards by means of the spectrophotometric test as described in Example 5.6.1.A) are pooled and the total volume of the pool is made to 7 ml; these 7 ml are injected onto a column packed with 8 ml of FMN-agarose; the column is washed with pH 6.8 50 mM bis-tris propane buffer, 1 mM DTT, 10% v/v glycerol, and then eluted with the same buffer containing 10  $\mu$ M FMN. The active fractions are pooled, desalted on PD-10 columns, injected in pH 8.2 50 mM Tris-HCl buffer, 5 mM DTT, 10% v/v glycerol onto a MonoQ HR 5/5 column and eluted with a linear KCl gradient (0 to 0.25 M).

After this step, the enzyme is pure. In SDS-PAGE electrophoresis, a single fairly broad band is seen, centred at a molecular weight estimated at 28,000, while, in Bio-Sil SEC 125 gel permeation chromatography, this protein forms a symmetrical peak centred around a molecular weight of approximately 30,000.

For sequencing, the protein is desalted on a 25-cm Vydac C4 column eluted with a linear gradient of from 30 to 70% of acetonitrile in water containing

0.07% of trifluoroacetic acid.

Table: Purification of FMN reductase

The purification factor is calculated from the increase in specific activity of the fractions during the purification.

20 5.6.2. Production of oligonucleotides from the protein sequence

This example describes how, starting from NH<sub>2</sub>-terminal and internal sequences of the protein FMN reductase, it is possible to synthesize oligo-

25 nucleotides

The NH<sub>2</sub>-terminal sequence of FMN reductase was deduced by microsequencing as described in Example 5.1.2. About 30 residues were identified in this way.

(NH<sub>2</sub>-Terminal sequences beginning at the 4th and at the 11th residue were also found in the sample sequenced.)

Two sequences internal to FMN reductase, of 13 and 21 amino acids, were also identified after trypsin hydrolysis and purification of fragments obtained on a Vydac C18 column.

5.6.3. Labelling of the mixtures of synthetic  
 15 oligonucleotides and hybridization of the genomic DNA  
 libraries of S. pristinaespiralis SP92.

This example describes how oligonucleotides  
 specific for a gene for the biosynthesis of  
 pristinamycins may be radioactively labelled and then  
 20 hybridized with membranes onto which DNA of genomic  
 libraries of S. pristinaespiralis has been transferred.

Labelling the oligonucleotides is carried out  
 by transfer at the 5'-terminal position of the  
 [ $\gamma$ -<sup>32</sup>P]phosphate group of ATP with T4 polynucleotide  
 25 kinase, as described in Example 5.1.3.

Approximately 2 x 500 ng of each mixture of  
 oligonucleotides were labelled in this way with <sup>32</sup>P and

were used to hybridize each of the two libraries.

Hybridization of the membranes of each library was carried out as described in Example 5.1.3.

5.6.4. Isolation of cosmid pIBV4 and  
5 determination of the region containing the structural  
gene for FMN reductase (snaC)

Cosmid pIBV4 was isolated from a clone of the  
library produced in E. coli strain HB101 which  
hybridized with all three mixtures of oligonucleotides  
10 simultaneously.

This cosmid was purified as described in  
Example 2. It contains a genomic DNA insert of S.  
pristinaespiralis SP92 whose size was estimated at  
48 kb. A map (Figure 7) was established from digestions  
15 with different restriction enzymes, as described in  
5.1.4.

Southern hybridizations of pIBV4 DNA,  
digested by means of different enzymes, with the  
mixtures of oligonucleotides enabled the region  
20 containing snaC, the structural gene for FMN reductase,  
to be identified. Southern blotting and hybridizations  
were carried out as described in Example 5.1.4.

-----The hybridization results enabled it to be  
shown that cosmid pIBV4 possessed a 4-kb BamHI-BamHI  
25 fragment containing the sequences homologous to the  
probes synthesized in Example 5.6.3.

5.7 Demonstration of the presence of the structural gene for p-aminophenylalanine (phenyl-N)-methyltransferase on cosmid pIBV2

This example illustrates how it is possible, starting from a purified protein, to identify the corresponding structural gene from among the genes which have already been analysed and sequenced as described in Examples 6.7 and 7.8 and which have also been expressed in E. coli as described in Example 11.

5.7.1. Identification and purification of the protein involved in the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine

This example illustrates how the protein responsible for the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine [p-aminophenylalanine (phenyl-N)-methyltransferase] may be purified to homogeneity from S. pristinaespiralis strain SP92, and how it may also be obtained pure from a recombinant strain of E. coli.

5.7.1.A. Assay of the activity of methylation of p-aminophenylalanine to p-methylaminophenylalanine and of the activity of methylation of p-methylaminophenylalanine to p-dimethylaminophenylalanine

This example illustrates the assay of two terminal activities of the biosynthesis of p-dimethylaminophenylalanine, a component of pristinamycin IA. These activities have never before been described, and possess the noteworthy property of being expressed only

during the period of production of pristinamycins. They are the methylation of p-aminophenylalanine to p-methylaminophenylalanine (methylation 1) on the one hand, and the methylation of p-methylaminophenylalanine to p-dimethylaminophenylalanine (methylation 2), both of these activities utilizing SAM as a methyl group donor (Figure 14).

The enzyme fractions to be assayed (1 to 20 units) are incubated for 30 min at 27°C in a total volume of 200 µl of pH 6.8 50 mM bis-tris propane buffer containing SAM (200 µM) in which the methyl group is radioactively labelled with isotope 14 of the carbon atom (2 Ci/mol), in the presence of p-amino-L-phenylalanine (1 mM) for the assay of methylation 1 or of p-methylamino-L-phenylalanine (2.5 mM) for the assay of methylation 2.

The reaction is stopped by adding 16 µl of 37% hydrochloric acid and then 20 µl of sodium heptane sulphonate as a concentration of 240 g/l. After centrifugation, 150 µl of supernatant are injected into the HPLC system in the following gradient mode:

- mobile phase: eluent A = 1.2 g of sodium heptanesulphonate + 2.5 ml of glacial acetic acid + water (qs 1000 ml)

eluent B = 1.2 g of sodium heptanesulphonate + 2.5 ml of

glacial acetic acid + 300 ml  
- of acetonitrile + water  
(qs 1000 ml)

	gradient: t(min)	%B
5	0	30
	16	30
	17	100
	20	100
	21	30
10	25	30

- stationary phase: 150 x 4.6 mm Nucleosil 5  $\mu$ m  
C18 column (Macherey-Nagel)

At outflow from the column, the substrates and products of the enzymatic reaction are quantified  
15 by absorption at 254 nm. This detection is coupled to an in-line radiochemical detection by means of a Berthold LB506 detector equipped with a type GT400-U4 solid scintillation cell. This enables the  
incorporation of radioactive methyl groups into the  
20 reaction products to be monitored specifically.

..... The unit of enzymatic activity for methylation 1 (for methylation 2) is defined as the amount of enzyme needed to incorporate 1 nmol of methyl groups into p-aminophenylalanine (into p-methylamino-  
25 phenylalanine).

## 5.7.1.B. Purification from

S. pristinaespiralis SP92 of the SAM-dependent N-methyltransferase catalysing the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine  
5 [p-aminophenylalanine (phenyl-N)-methyltransferase]

This experiment illustrates how an enzyme of S. pristinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IA may be purified.

10 Using the assay described above in Example 5.7.1.A, the purification of the SAM-dependent N-methyltransferase is carried out as described below, taking care to freeze and store the active fractions at -70°C between successive steps if necessary.

15 240 g of a centrifugation pellet, washed with pH 7.2 100 mM phosphate buffer, 1 mM PMSF, 5 mM EDTA, 5 mM EGTA, 0.5 M KCl, 10% v/v glycerol, of an S. pristinaespiralis SP92 culture harvested at the beginning of the pristinamycin production phase are  
20 taken up in 480 ml of pH 8.0 0.1 M Tris-HCl buffer containing 4 mM DTE, 5 mM benzamidine, 0.2 mM Pefabloc, 100 µg/l E-64, 2 mg/l leupeptin, 1 mM EDTA, 1 mM EGTA, 2 mg/l STT, 2 mg/l aprotinin, 20% v/v glycerol and  
25 + 4°C. The suspension thereby obtained is stirred vigorously at 4°C. After 30 min of stirring, 0.2 mg/ml deoxyribonuclease I and 5 mM MgCl<sub>2</sub> are added. After 90 min of stirring, the extract is centrifuged for

1 hour at 50,000 g. The supernatant is divided into 3 fractions of approximately 180 ml. Each one is desalted by gel permeation on a 500 ml column of Sephadex G-25 Fine equilibrated at the natural flow rate in pH 6.8 20 mM bis-tris buffer containing 4 mM DTE, 5 mM benzamidine, 0.2 mM Pefabloc, 100 µg/l E-64, 2 mg/l leupeptin, 1 mM EDTA, 1 mM EGTA, 2 mg/l STI, 2 mg/l aprotinin, 20% v/v glycerol. The protein eluate is then chromatographed (400 mg of protein at each cycle) on a MonoQ HR 16/10 column at a flow rate of 6 ml/min with an increasing linear gradient of sodium chloride (0 to 0.3 M) in pH 6.8 20 mM bis-tris buffer containing 4 mM DTE, 2 mM benzamidine, 100 µg/l E-64, 2 mg/l leupeptin, 20% v/v glycerol. At outflow from the column, the fractions are supplemented with 10% v/v of pH 6.8 20 mM bis-tris buffer containing 4 mM DTE, 30 mM benzamidine, 2 mM Pefabloc, 100 µg/l E-64, 2 mg/l leupeptin, 5 mM EDTA, 5 mM EGTA, 10 mg/l STI, 10 mg/l aprotinin, 20% v/v glycerol. Under these conditions, both methylation activities (1 and 2) are detected identically in the exclusion fractions and the first elution fractions. These fractions are pooled and concentrated by ultrafiltration on CentriPrep 10. This concentrate is made to 0.85 M ammonium sulphate and then chromatographed (20 to 80 mg at each cycle) on a Phenyl Superose HR 10/10 column at a flow rate of 1 ml/min with a decreasing linear gradient of ammonium sulphate (0.85 to 0 M) in pH 6.8 50 mM bis-tris buffer

containing 4 mM DTE, 2 mM benzamidine, 100 µg/l E-64, 2 mg/l leupeptin, 1 mM EDTA, 1 mM EGTA, 10% v/v glycerol. At outflow from the column, the fractions are supplemented with 10% v/v of pH 6.8 50 mM bis-tris

5 buffer containing 4 mM DTE, 30 mM benzamidine, 2 mM Pefabloc, 100 µg/l E-64, 2 mg/l leupeptin, 1 mM EDTA, 1 mM EGTA, 10 mg/l STI, 10 mg/l aprotinin, 10% v/v glycerol. Under these conditions, both methylation activities (1 and 2) are detected identically in the

10 elution fractions corresponding to approximately 0.15 M ammonium sulphate. These fractions are pooled, concentrated by ultrafiltration on Centricon 10, desalted on PD-10 columns equilibrated in pH 8.2 (at 5°C) 50 mM Tris buffer containing 4 mM DTE, 2 mM

15 benzamidine, 100 µg/l E-64, 2 mg/l leupeptin, 20% v/v glycerol, and then chromatographed (approximately 10 mg at each cycle) on a MonoQ HR 5/5 column equilibrated in the same buffer at a flow rate of 1 ml/min. Under these conditions, the two activities are not retained on the

20 column. At outflow from the column, the exclusion fractions hence containing these two activities are supplemented with 10% v/v of pH 8.2 50 mM Tris buffer containing 4 mM DTE, 30 mM benzamidine, 2 mM Pefabloc, 100 µg/l E-64, 2 mg/l leupeptin, 1 mM EDTA, 1 mM EGTA,

25 20% v/v glycerol. These fractions are then concentrated by ultrafiltration on Centricon 10 and thereafter chromatographed on a 300 x 7.5 mm 10 µm TSK G2000 SW column equilibrated at a flow rate of 0.5 ml/min in

pH 7.0 50 mM Hepes buffer containing 4 mM DTE, 0.2 mM Pefabloc, 1 mM EDTA, 1 mM EGTA, 10% v/v glycerol, 0.15 M sodium chloride. The two activities co-elute in this technique at a retention time corresponding to a molecular weight close to 30,000. After this step, a preponderant protein is visible in SDS-PAGE. It is located at around 32,000.

Table: Purification of the enzyme methylating p-aminophenylalanine to p-dimethylaminophenylalanine

Purification Steps	Vol. (ml)	Protein (mg)	Sp.Act. (units <sup>a</sup> /mg)	Yield (%)	Purification factor
Crude extract	510	1800	29	-	-
G-25 Fine	560	1560	34	102	1.17
MonoQ HR 16/10	670	82	430	67	14.8
Phenyl Superose	10	3.48	6300	42	217
MonoQ HR 5/5	7	0.88	17200	29	593
TSK G2000	0.8	0.113	40300	8.7	1390

<sup>a</sup>This refers to units of enzymatic activity for methylation 1. At each step, the value of the units of enzymatic activity for methylation 2 was equal to 120% of that of the units for methylation 1.

The purification factor is calculated from the increase in specific activity of the fractions during the purification.

5.7.1.C. Purification from E. coli pVRC706 of the recombinant protein of S. pristinaespiralis SP92 displaying the SAM-dependent N-methyltransferase

activity catalysing the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine

This experiment illustrates how an enzyme of S. prisinaespiralis SP92 participating in the biosynthesis pathway of pristinamycin IA and expressed in E. coli by cloning of the papM gene may be purified.

Using the assay described above in Example 5.7.1.A., we showed that crude extracts of the recombinant strain E. coli::pVRC706 display a strong activity for methylation 1 and for methylation 2, whereas in the control E. coli strain (pMTL23) neither of these two activities was detected. The purification of the SAM-dependent p-aminophenylalanine (phenyl-N)-methyltransferase catalysing the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine was then carried out.

Under the same conditions as those described in Example 5.7.1.B., except for a chromatography step which was eliminated (step of purification on MonoQ HR 5/5), we purified to homogeneity a protein which possesses a molecular weight in chromatography on a TSK G2000 column and in SDS-PAGE identical to those possessed by the protein purified in Example 5.7.1.B.

Table: Purification of the enzyme methylating  
p-aminophenylalanine to p-dimethylaminophenylalanine  
from E. coli strain pVRC706

Purification Steps	Vol. (ml)	Protein (mg)	Sp.Act. (units <sup>a</sup> /mg)	Yield (%)	Purification factor
Crude extract	15	190	235	-	-
G-25 Fine	22	175	231	91	1
MonoQ HR 16/10	24	13.4	2100	63	8.9
Phenyl Superose	3.0	0.39	35500	31	145
TSK G2000	0.8	0.092	45200	9.3	192

<sup>a</sup>This refers to units of enzymatic activity for methylation 1. At each step, the value of the units of enzymatic activity for methylation 2 was equal to 120% of that of the units for methylation 1.

The purification factor is calculated from the increase in specific activity of the fractions during the purification.

5.7.2. Identification of the structural gene for p-aminophenylalanine (phenyl-N)-methyltransferase

The NH<sub>2</sub>-terminal sequence of the 32,000 protein purified in Example 5.7.1.B was determined by microsequencing as described in Example 5.1.2. Ten residues were determined in this way:

TAAAPTLAQA

The NH<sub>2</sub>-terminal sequence of the 32,000 protein purified in Example 5.7.1.C was determined by

microsequencing as described in Example 5.1.2. Ten residues were determined in this way:

TAAAPTLAQA

In both cases the same residues are found, and this sequence corresponds exactly to the beginning of the protein sequence which is deduced from the sequence of the papM gene (see residues 2 to 11 on SEQ ID no. 10). The purified p-aminophenylalanine (phenyl-N)-methyltransferase is hence the protein PapM.

EXAMPLE 6: Subcloning of DNA fragments cloned into cosmids as prepared in Example 3 and containing the genes of interest

This example illustrates how, starting from cosmids constructed as described in Example 3 and containing genes for the biosynthesis of pristinamycins II or pristinamycins I, it is possible to subclone DNA fragments containing these genes.

These subclonings were performed in order to be able to deduce subsequently the nucleic acid sequence of the genes identified, as well as to carry out the different construction presented in the examples which follow.

6.1. Isolation of the 5.5-kb EcoRI-BglII fragment containing the structural gene for 3-hydroxypicolinic acid:AMP ligase

This example describes how, starting from cosmid pIBV2 containing the structural gene for 3-hydroxypicolinic acid:AMP ligase, it is possible to

subclone a DNA fragment of smaller size containing this gene.

Approximately 10 µg of cosmid pIBV2 were cut successively with the restriction enzymes BglII and EcoRI (New England Biolabs) under the conditions recommended by the supplier. The restriction fragments thereby obtained were separated by electrophoresis on 0.8% agarose gel, and the 5.5-kb BglII-EcoRI fragment was isolated by electroelution as described in Maniatis et al. (1989).

Approximately 100 ng of pUC19 (Viera and Messing 1982) cut with BamHI and EcoRI were ligated with 200 ng of the 5.5-kb BglII-EcoRI fragment under the conditions described in Example 3.3.

After transformation of the strain TGI and selection of the transformants on solid LB medium containing 150 µg/ml of ampicillin and 20 µg/ml of X-gal according to the technique described by Maniatis et al. (1989), a clone carrying the desired fragment was isolated. The recombinant plasmid was designated pVRC402. Its restriction map is presented in Figure 15(A). It was shown by hybridization, in Example 5.2., that the 5.5-kb EcoRI-BglII fragment contains the structural gene for S. pristinaespiralis SP92 3-hydroxypicolinic acid:AMP ligase. Plasmid pVRC402 hence contains the structural gene for S. pristinaespiralis SP92 3-hydroxypicolinic acid:AMP ligase.

6.2. Isolation of a 4.6-kb BglII-BglII  
fragment from cosmid pIBV2

This example describes how, starting from cosmid pIBV2, it is possible to subclone a DNA fragment of smaller size for the purpose of identifying, in the regions adjacent to the structural gene for 3-hydroxypicolinic acid:AMP ligase, the presence of other genes involved in the biosynthesis of pristinamycins I.

The different cloning steps were carried out as described above.

Approximately 10 µg of cosmid pIBV2 were cut with BglII. The restriction fragments thereby obtained were separated by electrophoresis on 0.8% agarose gel, and the 4.6-kb BglII-BglII fragment was isolated by electroelution.

Approximately 100 ng of pUC19 cut with BamHI were ligated with 200 ng of the BglII-BglII fragment.

A clone carrying the desired fragment was isolated after transformation of the strain TG1 as described in Example 6.1. The recombinant plasmid was designated pVRC501. Its restriction map is presented in Figure 15(B).

6.3. Isolation of the 6-kb BamHI-BamHI  
fragment containing the structural genes for the two  
subunits of pristinamycin IIA synthase

This example describes how, starting from cosmid pIBV1, it is possible to subclone a DNA fragment

of smaller size containing the structural genes for the two subunits of pristinamycin IIA synthase.

The different cloning steps were carried out as described above.

5            Approximately 10 µg of cosmid pIBV1 were cut with BamHI. The restriction fragments thereby obtained were separated by electrophoresis on 0.8% agarose gel, and the 6-kb BamHI fragment was isolated by electroelution.

10           Approximately 100 ng of pBKS<sup>-</sup> (Stratagene Cloning Systems, La Jolla California) cut with BamHI were ligated with 200 ng of the 6-kb BamHI fragment.

             A clone carrying the desired fragment was isolated after transformation of the strain TG1. The  
15 recombinant plasmid was designated pXL2045. Its restriction map is presented in Figure 16. It was shown by hybridization, in Example 5.1, that the 6-kb BamHI fragment contains the snaA and snaB genes coding for the two subunits of S. pristinaespiralis SP92  
20 pristinamycin IIA synthase. Plasmid pXL2045 hence contains the snaA and snaB genes coding for the two subunits of S. pristinaespiralis SP92 pristinamycin IIA synthase.

6.4. Isolation of the 6.2-kb SphI fragment  
25 containing a portion of the structural gene for  
pristinamycin I synthase II

             This example describes how, starting from cosmid pIBV3, it is possible to subclone a DNA fragment

of smaller size containing a portion of the structural gene for pristinamycin I synthase II.

The different cloning steps were carried out as described above.

5            Approximately 10 µg of cosmid pIBV3 were cut with SphI. The restriction fragments thereby obtained were separated on 0.8% agarose gel, and the 6.2-kb SphI fragment was isolated by the technique of the "Geneclean" kit marketed by the company Biol01-Ozyme.

10           Approximately 100 ng of pUC19 cut with SphI were ligated with 200 ng of the 6.2-kb SphI fragment.

A clone carrying the desired fragment was isolated after transformation of the strain TG1. The recombinant plasmid was designated pVRC1105. Its  
15           restriction map is presented in Figure 17.

6.5. Isolation of the 8.4-kb SphI fragment containing a portion of the structural gene for pristinamycin I synthase III

             This example describes how, starting from  
20           cosmid pIBV3, it is possible to subclone a DNA fragment of smaller size containing a portion of the structural gene for pristinamycin I synthase III.

             The different cloning steps were carried out as described above.

25           Approximately 10 µg of cosmid pIBV3 were cut with SphI. The restriction fragments thereby obtained were separated on 0.8% agarose gel, and the 8.4-kb SphI fragment was isolated by the technique of the

"GeneClean" kit marketed by the company Bio101-Ozyme.

Approximately 100 ng of pUC19 cut with SphI were ligated with 200 ng of the 8.4-kb SphI fragment.

5 A clone carrying the desired fragment was isolated after transformation of the strain TG1. The recombinant plasmid was designated pVRC1106. Its restriction map is represented in Figure 18.

6.6. Isolation of a 6.6-kb SphI fragment containing a portion of the structural gene for  
10 pristinamycin I synthase IV

This example describes how, starting from cosmid pIBV3, it is possible to subclone a DNA fragment of smaller size containing a portion of the structural gene for pristinamycin I synthase IV.

15 The different cloning steps were carried out as described above.

Approximately 10 µg of cosmid pIBV3 were cut with SphI. The restriction fragments thereby obtained were separated on 0.8% agarose gel, and the 6.6-kb SphI  
20 fragment was isolated by the technique of the "GeneClean" kit marketed by the company Bio101-Ozyme.

Approximately 100 ng of pUC19 cut with SphI were ligated with 200 ng of the 6.6-kb SphI fragment.

A clone carrying the desired fragment was  
25 isolated after transformation of the strain TG1. The recombinant plasmid was designated pVRC1104. Its restriction map is presented in Figure 19.

6.7 Isolation of the 17-kb HindIII-HindIII fragment containing cosmid pHC79 and carrying the genes located upstream of 3-hydroxypicolinic acid:AMP ligase (pristinamycin I synthase I)

5           This example describes how, starting from cosmid pIBV2 containing the structural gene for 3-hydroxypicolinic acid:AMP ligase, it is possible to delete a large portion of this cosmid and retain only the portion located upstream of 3-hydroxypicolinic  
10   acid:AMP ligase.

          Approximately 200 ng of cosmid pIBV2 were cut with the restriction enzyme HindIII. The enzyme was denatured for 30 min at 85°C as recommended by the supplier. Cosmid pIBV2 digested in this way was  
15   precipitated with ethanol as described in Maniatis et al. (1989) and religated with itself in a volume of 50 µl.

          After transformation of the strain TG1 and selection of the transformants on solid LB + 150 µg/ml  
20   of ampicillin according to the technique described by Maniatis et al. (1989), a clone containing cosmid pHC79 and the portion located upstream of 3-hydroxypicolinic acid:AMP ligase (the whole corresponding to a size of approximately 17 kb) was isolated. The recombinant  
25   plasmid was designated pVRC900. Its restriction map is presented in Figure 20.

6.8. Isolation of the 1.4-kb BamHI-SstI  
fragment originating from cosmid pIBV3

This example describes how, starting from cosmid pIBV3 containing the snaA gene coding for the large subunit of PIIA synthase, it is possible to subclone a DNA fragment located upstream in order to study and sequence it.

Approximately 10 µg of cosmid pIBV3 were cut successively with the restriction enzymes SstI and BamHI. The restriction fragments thereby obtained were separated on 0.8% agarose gel, and the 1.4-kb BamHI-SstI fragment was isolated by the technique of the "Geneclean" kit marketed by the company Biol01-Ozyme.

Approximately 100 ng of pDH5 (Hilleman *et al.* 1991) cut with BamHI and SstI were ligated with 200 ng of the BamHI-SstI fragment under the conditions described in Example 3.3.

After transformation of the strain TG1 and selection of the transformants of solid LB + 150 µg/ml of ampicillin + X-gal according to the technique described by Maniatis *et al.* (1989), a clone carrying the desired fragment was isolated. The recombinant plasmid was designated pVRC1000. Its restriction map is represented in Figure 21.

6.9. Isolation of the 4-kb BamHI-BamHI  
fragment containing the structural gene for FMN  
reductase

This example describes how, starting from

cosmid pIBV4 containing the structural gene for FMN reductase (snaC), it is possible to subclone a DNA fragment of smaller size containing this gene.

5 The different cloning steps were carried out as described above.

Approximately 10 µg of cosmid pIBV4 were cut with the restriction enzyme BamHI. The restriction fragments thereby obtained were separated on 0.8% agarose gel, and the 4-kb BamHI-BamHI fragment was  
10 isolated by electroelution.

Approximately 100 ng of pUC19 cut with BamHI were ligated with 200 ng of the 4-kb BamHI-BamHI fragment.

After transformation of *E. coli* strain DH5α  
15 (supE44 DlacU169 (f80lacZDM15) hsdR17 recA1 endA1 gyrA96 thi-1 relA1) (Hanahan, 1983) and selection of the transformants on solid LB + 150 µg/ml of ampicillin + X-gal according to the technique described by Maniatis et al. (1989), a clone carrying the desired  
20 fragment was isolated. The recombinant plasmid was designated pVRC509. Its restriction map is presented in Figure 22.

-----EXAMPLE 7: Sequence of the isolated DNA fragments containing the genes for the biosynthesis of  
25 pristinamycins of S. pristinaespiralis SP92

This example illustrates the sequencing of DNA fragments carrying, on the one hand genes involved in the biosynthesis of pristinamycins of the

pristinamycin I family, and on the other hand genes involved in the biosynthesis of pristinamycins of the pristinamycin II family, of the S. pristinaespiralis strain.

5            7.1. Sequencing of a 5-kb BamHI-XhoI fragment

This example illustrates how the nucleotide sequence of a fragment containing the snaA and snaB genes of S. pristinaespiralis SP92 may be obtained.

10           The BamHI-XhoI fragment is part of the 6-kb BamHI-BamHI fragment which was cloned into phasmid pBKS- to give plasmid pXL2045 described in Example 6.3.

Subfragments of this 5-kb BamHI-XhoI insert were then obtained by enzymatic digestion and thereafter subcloned into phages M13mp18 or M13mp19 (Messing et  
15 al, 1981) in both orientations. The subcloning sites used are the following: EcoRI, PstI, PstI, NruI, EcoRI, NruI, NotI, SalI, SstI, XhoI, SalI and XhoI, and are shown in Figure 16.

20           These different inserts were sequenced by the chain-termination reaction method, using as a synthetic primer the universal primer (Maniatis et al, 1989) or oligonucleotides which are synthesized (as is described in Example 5) and are complementary to a sequence of 20 nucleotides of the insert to be sequenced.

25           The overlap between these different inserts enabled the total nucleotide sequence to be established on both strands of the BamHI-XhoI fragment which comprises 5392 bp (SEQ ID no. 1).

7.2. Sequencing of a region of 1870 bp of the  
5.5-kb EcoRI-BglII fragment

This example illustrates how the nucleotide  
sequence of a fragment containing the snbA gene of S.  
5 pristinaespiralis SP92 may be obtained.

The region of 1870 bp sequenced is part of  
the 5.5-kb EcoRI-BglII fragment which was cloned into  
plasmid pUC19 to give plasmid pVRC402 described in  
Example 6 (Figure 15(A)). Subfragments of the 5.5-kb  
10 EcoRI-BglII insert were obtained by enzymatic cleavage  
and then subcloned into phages M13mpl8 or M13mpl9 in  
both orientations. The subcloning sites are HindIII,  
PstI and HindIII, and are shown in Figure 15(A).

The overlap between these fragments enabled  
15 the total sequence of the Sau3A-Sau3A region, which  
comprises 1870 bp (SEQ ID no. 5), to be established.

7.3. Sequence of a region of 1830 bp in the  
4.6-kb BglIII-BglIII fragment

This example illustrates how the nucleotide  
20 sequence of a fragment adjacent to that which contains  
the snbA gene of S. pristinaespiralis SP92 may be  
obtained.

-----This sequence was deduced by subcloning the  
1-kb BamHI-PstI and 2.1-kb PstI-EcoRI fragments (Figure  
25 15(B)) from pVRC501 (Example 6) into the vectors  
M13mpl8 and M13mpl9. The PstI site was traversed by  
subcloning a 423-bp Sau3A-Sau3A fragment overlapping  
this site, followed by sequencing. The sequence of

1830 bp thereby obtained is shown in (SEQ ID no. 6).

7.4. Sequencing of two regions of 227 bp and 247 bp of the 6.2-kb SphI fragment

5 This example illustrates how the nucleotide sequence of fragments containing a portion of the structural gene for pristinamycin I synthase II (snbC) of S. pristinaespiralis may be obtained.

10 The regions of 227 and 247 bp sequenced are parts of the 6.2-kb SphI fragment which was cloned into plasmid pUC19 to give plasmid pVRC1105 described in Example 6.4 (Figure 17). Subfragments of the 6.2-kb SphI insert were obtained by enzymatic cleavage and then subcloned into phages M13mp18 or M13mp19 in both orientations. The subcloning sites are XhoI, PstI and 15 BglII, and are shown in Figure 17. The 227-bp PstI-BglII fragment was sequenced completely, and 247 bp were sequenced from the 900-bp XhoI fragment: these sequences are presented in SEQ ID nos. 11 and 12.

20 7.5. Sequencing of two regions of 192 bp and 474 bp of the 8.4-kb SphI fragment

This example illustrates how the nucleotide sequence of fragments containing portions of the structural gene for pristinamycin I synthase III (snbD) of S. pristinaespiralis may be obtained.

25 The regions of 192 and 474 bp sequenced are parts of the 8.4-kb SphI fragment which was cloned into plasmid pUC19 to give plasmid pVRC1106 described in Example 6.5 (Figure 18). Subfragments of the 8.4-kb

SphI insert were obtained by enzymatic cleavage and then subcloned into phages M13mp18 or M13mp19 in both orientations. The subcloning sites are XhoI, PstI, SphI and BglII, and are shown in Figure 18.

5           The 192-bp BglII-SphI and 474-bp PstI-XhoI fragments were sequenced completely: these sequences are presented in SEQ ID nos. 13 and 14.

7.6 Sequencing of two regions of 485 bp and 291 bp of the 6.6-kb SphI fragment

10           This example illustrates how the nucleotide sequence of fragments containing portions of the structural gene for pristinamycin I synthase IV (snbE) of S. pristinaespiralis may be obtained.

          The regions of 291 and 485 bp sequenced are  
15 parts of the 6.6-kb SphI fragment which was cloned into plasmid pUC19 to give plasmid pVRC1104 described in Example 6.6 (Figure 19). Subfragments of the 6.6-kb SphI insert were obtained by enzymatic cleavage and then subcloned into phages M13mp18 or M13mp19 in both  
20 orientations. The subcloning sites are XhoI, PstI and SphI, and are shown in Figure 19. The 485-bp XhoI-SphI fragment was sequenced completely, and 291 bp were sequenced from the 1500-bp PstI fragment: these sequences are presented in SEQ ID nos. 15 and 16.

25           7.7. Sequence of a region of 645 bp in a 3.4-kb XhoI-XhoI fragment isolated from pVRC900

          This example illustrates how the nucleotide sequence of a fragment located upstream of that which

contains the snbA gene of S. pristinaespiralis may be obtained.

To deduce this sequence, the 3.4-kb XhoI-XhoI fragment was subcloned beforehand into the vector pUC18 from the vector pVRC900 described in 6.7. The different cloning steps were carried out as described in 6.1: plasmid pVRC900 was digested with the restriction enzyme XhoI, and the fragments thereby obtained were separated on 0.8% agarose gel. The 3.4-kb XhoI-XhoI fragment was purified by electroelution and was ligated with pUC18 cut with the restriction enzyme SalI. After transformation into TG1, a clone carrying the 3.4-kb XhoI-XhoI fragment was isolated. The recombinant plasmid was referred to as pVRC903. Its restriction map is presented in Figure 23.

The 645-bp sequence was then deduced by subcloning the 1.4-kb PvuII-EcoRI and 0.9-kb PvuII-EcoRI fragments (Figure 23) from pVRC903 described above into the vectors M13mp18 and M13mp19. To carry out these clonings, the vectors M13mp18 and M13mp19 were first digested with the restriction enzyme BamHI; the cohesive ends thereby liberated were filled in with the large fragment of DNA polymerase I (Klenow: New England Biolabs) according to the technique described by Maniatis et al. (1989) so as to generate blunt ends compatible with the ends liberated by PvuII digestion; the vectors were then digested with the restriction enzyme EcoRI. The PvuII site was traversed by

subcloning a 2.2-kb PstI-PstI fragment, isolated from pVRC903, overlapping this site. The sequence of 645 bp thereby obtained is shown in SEQ ID no. 9.

7.8. Sequence of a region of 1050 bp in a

5 4.1-kb PstI-PstI fragment isolated from pVRC900

This example illustrates how the nucleotide sequence of a fragment located upstream of that which contains the snbA gene of S. pristinaespiralis may be obtained.

10 To deduce this sequence, a 4.1-kb PstI-PstI fragment was subcloned beforehand into the vector pUC19 from the vector pVRC900 described in 6.7. The different cloning steps were carried out as described in 6.1.

Plasmid pVRC900 was digested with restriction enzyme  
15 PstI, and the fragments thereby obtained were separated on 0.8% agarose gel. The 4.1-kb PstI-PstI fragment was purified by electroelution and was ligated with pUC19 cut with the restriction enzyme PstI. After transformation into TG1, a clone carrying the 4.1-kb  
20 PstI-PstI fragment was isolated. The recombinant plasmid was referred to as pVRC409. Its restriction map is presented in Figure 24.

----- This sequence was then deduced by subcloning the 0.7-kb XhoI-XhoI and 1-kb XhoI-StuI fragments  
25 (Figure 24) from pVRC409 described above into the vectors M13mp18 and M13mp19. The XhoI site internal to the sequence was traversed by double-strand sequencing from plasmid pVRC409. The sequence of 1050 bp thereby

obtained is shown in SEQ ID no. 10.

7.9. Sequence of a region of 640 bp in the  
1.4-kb BamHI-SstI fragment

5 This example illustrates how the nucleotide  
sequence of a fragment adjacent to that which contains  
the snaA and snaB genes of S. pristinaespiralis coding  
for the two subunits of PIIA synthase may be obtained.

This sequence was deduced by subcloning the  
1.4-kb BamHI-SstI fragment (Figure 21) from pVRC1000  
10 (Example 6.8) into the vectors M13mp18 and M13mp19 (see  
Example 7.1). The sequence of 640 bp obtained is shown  
in SEQ ID no. 8.

7.10. Sequencing of the XhoI-KpnI region of  
694 bp present in the 4-kb BamHI-BamHI fragment

15 This example illustrates how the nucleotide  
sequence of a fragment containing the snaC gene of S.  
pristinaespiralis may be obtained.

The region of 694 bp sequenced is part of the  
4-kb BamHI-BamHI fragment which was cloned into plasmid  
20 pUC19 to give plasmid pVRC509 described in Example 6.9.  
A 694-bp XhoI-KpnI fragment, obtained by double  
digestion of plasmid pVRC509 with the restriction  
enzymes XhoI and KpnI and which hybridizes with the  
3 oligonucleotide probes described in 5.6, was cloned  
25 into phages M13mp18 and M13mp19. The XhoI and KpnI  
subcloning sites are shown in Figure 22.

The sequence of the 694-bp fragment thereby  
obtained is presented in SEQ ID no. 7.

EXAMPLE 8: Analysis of the nucleotide sequences by determination of the open reading frames

This example illustrates how it is possible to determine the open reading frames present in the nucleotide sequences defined in Example 7, and to identify the genes involved in the biosynthesis of pristinamycins I and pristinamycin II of S. pristinaespiralis SP92 as well as the polypeptides encoded by these genes.

8.1. 5-kb BamHI-XhoI fragment (pXL2045)

This example illustrates how it is possible to determine the open reading frames present within the 5-kb BamHI-XhoI fragment isolated above and sequenced as described in Examples 6 and 7.

We looked for the presence of open reading frames within the 5-kb BamHI-XhoI fragment utilizing the fact that Streptomyces DNA has a high percentage of G and C bases as well as a strong bias in the use of the codons of which the coding frames are composed (Bibb et al. 1984). The Staden and McLachlan (1982) method enables the probability of the coding frames to be calculated on the basis of the use of the codons of Streptomyces genes which are already sequenced and collated in a file containing 19673 codons obtained from the BISANCE data-processing server (Dessen et al. 1900)..

This method enabled four highly probable open reading frames, which are shown in the following table,

to be characterized within the 5-kb BamHI-XhoI fragment. They are designated frames 1 to 4 according to their position starting from the BamHI site. For each one, their length in bases, their position within the fragment (the BamHI site being located at position 1) and also the molecular weight in kDa of the corresponding protein are given. Frames 1, 3 and 4 are coded by the same strand and frame 2 by the complementary strand (Figure 16).

10

15

Frame number and gene name	Position	number of nucleotides	number of amino acids	MW in kDa of the protein encoded
1 ( <u>snaA</u> )	48-1313	1266	422	46.5
2	2530-1328	1203	401	-
3 ( <u>snaB</u> )	(inv) 2692-	831	277	29
4 ( <u>samS</u> )	3522	1206	402	43
	3558-4763			

- Frames 1 and 3 correspond respectively to the proteins SnaA (SEQ ID no. 2) and SnaB (SEQ ID no. 3) isolated above as described in Example 5 and for

which the cloning of the genes is detailed in Example 6. In effect, the NH<sub>2</sub>-terminal sequences of the products of ORFs 1 and 3 are identical to the NH<sub>2</sub>-terminal sequences found for the proteins SnaA and SnaB, respectively, in Example 5.1.2, apart from the amino-terminal methionine which has been excized. Moreover, the molecular masses calculated from the sequences are comparable to the apparent molecular masses of the proteins SnaA and SnaB, estimated, respectively, in SDS-PAGE as described in Example 5.

- Comparison of the product of open reading frame no. 4 with the protein sequences contained in the NBRF bank reveals a homology with various S-adenosylmethionine (or SAM) synthases, in particular of E. coli (Markham et al., (1984), of rat (Horikawa et al., 1989) and of S. cerevisiae (Thomas et al., 1988). The percentage homology values calculated over the whole of the sequence using Kanehisa's (1984) algorithm vary from 51.8 to 55.4%.

These sequence comparisons hence enable it to be demonstrated that the product of open reading frame no. 4 is an SAM synthase involved in the biosynthesis of pristinamycins I or II. This gene was designated SamS (SEQ ID no. 4).

The demonstration of the involvement of the SamS gene in the biosynthesis of pristinamycins is confirmed by the construction of the SP92 mutant disrupted in this gene, as described in Example 9.2.

- Comparison of the sequence of the product of open reading frame no. 2 with the protein sequences contained in the Genpro bank reveals that an internal portion of this protein is 36% homologous with an internal portion of the first open reading frame of the insertion sequence (IS891) of Anabaena (Bancroft and Wolk, 1989). This result suggests that open reading frame no. 2, designated ORF 401, belongs to an insertion sequence, and that there is hence an insertion sequence located between the snaA and snaB genes.

#### 8.2. 1870-bp Sau3A-Sau3A fragment (pVRC4021)

This example illustrates how it is possible to determine open reading frames present within the 1870-bp Sau3A-Sau3A fragment isolated above and sequenced as described in Examples 6 and 7.

The search for open reading frames for the Sau3A-Sau3A fragment was performed as above. A single complete open reading frame could be demonstrated in this way. Its characteristics are as follows: this frame extends from position 109 to position 1858 of the Sau3A-Sau3A fragment, which corresponds to a frame of 1749 bases coding for a protein of 582 amino acids having a molecular mass of 61400 Da. This protein corresponds to the protein SnaA purified above as described in Example 5 and for which the cloning of the gene is detailed in Example 6. In effect, the NH<sub>2</sub>-terminal sequence of the product of the ORF present

on the Sau3A-Sau3A fragment is identical to the NH<sub>2</sub>-terminal sequence found for the protein SnbA in Example 5.2. The molecular mass of 61400 Da calculated from the sequence is comparable to the apparent molecular mass of the protein SnbA, estimated at 67000 Da in SDS-PAGE and at 60000 Da by gel permeation as described in Example 5.2.1.B.

The snbA gene hence codes for the enzyme which catalyses the formation of the acyladenylate 3-hydroxypicolinyl-AMP from one molecule of 3-hydroxypicolinic acid and one molecule of ATP: 3-hydroxypicolinic acid:AMP ligase (SEQ ID no. 5).

### 8.3. 1830-bp fragment (pVRC501)

This example illustrates how it is possible to determine the open reading frames present within the 1830-bp fragment sequenced from the 3.1-kb BamHI-EcoRI fragment isolated above.

The search for open reading frames for the 1830-bp fragment was performed as above. A single complete open reading frame could be demonstrated in this way. Its characteristics are as follows: the probable beginning of this frame is located at position 103 and the end at position 1686 of the region of 1830 bp sequenced from the BamHI-EcoRI fragment, which corresponds to a protein of 528 amino acids having an approximate molecular weight of 54000.

Comparison of the sequence of this protein with the sequences contained in the Genepro bank

reveals that it is homologous to proteins having a transport function for various metabolites, in particular for tetracycline in various microorganisms (Khan and Novick, 1983; Hoshino et al., 1985),  
5 actinorhodine (Fernandez-Moreno et al., 1991) and methylenomycin (Neal and Chater, 1987b) in S. coelicolor.

These data indicate that the product of the open reading frame contained in the 3.1-kb BamHI-EcoRI  
10 fragment is a transport protein enabling pristinamycins I (and possibly pristinamycins II) to be exported out of the cell. This protein was designated SnbR and the corresponding gene snbR (SEQ ID no. 6).

Analysis of the hydrophobicity profile of the  
15 protein SnbR by the method of Kyte and Doolittle (1982) corroborates its membrane localization and hence its transport function.

#### 8.4. 1050-bp fragment (pVRC409)

This example illustrates how it is possible  
20 to determine the open reading frames present within the 1050-bp fragment sequenced above from pVRC409 as described in Example 7.8.

— The search for open reading frames for the 1050-bp fragment was performed as above. A single  
25 complete open reading frame could be demonstrated in this way. Its characteristics are as follows: this phase extends from position 84 to position 962 of the sequenced portion, which corresponds to a frame of

878 bases coding for a protein of 292 amino acids having a molecular mass of 32000 Da. This protein was referred to as protein PapM. It was, moreover, purified from S. pristinaespiralis strain SP92 as described in Example 5. The molecular mass of 32000 Da calculated from the sequence is identical to the apparent molecular mass of 32000 Da estimated on SDS-PAGE as described in Example 5. Moreover, the NH<sub>2</sub>-terminal sequence of this protein, deduced as described in Example 5, corresponds well to the NH<sub>2</sub>-terminal sequence of the protein PapM identified by analysis of the open reading frames of the sequence of 1050 bp (SEQ ID no. 10).

#### 8.5. 220-bp and 247-bp fragments (pVRC1105)

This example illustrates how it is possible to determine the open reading frames present within the 227-bp and 247-bp fragments sequenced from pVRC1105 as described in Examples 6 and 7.

The search for open reading frames for these two fragments was performed as above. An incomplete reading frame could be demonstrated in both cases over the whole length of the fragment.

The sequence obtained from the open reading frame identified on the 247-bp fragment isolated from the 900-bp XhoI fragment contains one of the internal sequences of the protein SnbC purified as described in Example 5.

Comparison of the product of the open reading

frames identified on the 227-bp and 247-bp fragments isolated from pVRC1105 with sequences of the Genpro bank reveals that they are homologous to peptide synthases. The one deduced from the 227-bp fragment displays 24.5% homology with Acremonium chrysogenum ( $\alpha$ -aminoadipyl)cysteinyvaline synthetase (Gutierrez et al. 1991). The one deduced from the 247-bp fragment displays 34.9% homology with Bacillus gramicidin S synthase II (Hori et al. 1991) and 28% homology with Acremonium chrysogenum ( $\alpha$ -aminoadipyl)cysteinyvaline synthetase (Gutierrez et al. 1991).

This confirms that cosmid pIBV3 isolated in Example 5.1 does indeed contain a portion of the structural gene for pristinamycin I synthase II described in Example 5.3, designated SnbC (SEQ ID no. 11 and 12).

#### 8.6. 192-bp and 474-bp fragments (pVRC1106)

This example illustrates how it is possible to determine the open reading frames present within the 192-bp and 474-bp fragments sequenced from pVRC1106 as described in Examples 6 and 7.

To search for open reading frames for these two fragments was performed as above. An incomplete reading frame could also be demonstrated on the 192-bp fragment isolated from pVRC1106. Its characteristics are as follows: this frame begins at position 29 of the portion sequenced in the direction of BglII. No stop codon was identified, indicating that this open frame

is not terminated.

The sequence obtained from the open reading frame identified on the 192-bp BglII-SphI fragment contains the internal sequence of the protein SnbD purified as described in Example 5, which proves, in fact, to be the NH<sub>2</sub>-terminal sequence of the protein.

An incomplete reading frame could be demonstrated over the whole length of the 474-bp XhoI-PstI fragment.

Comparison of the product of the open reading frame identified on the 474-bp fragment isolated from pVRC1106 with the sequences of the Genpro bank reveals that this protein fragment displays from 30 to 40% homology with peptide synthases, for example 39.4% with *Bacillus* gramicidin S synthase II (Hori *et al.* 1991) and 34% with *Acremonium chrysogenum* ( $\alpha$ -aminoadipyl)cysteinyvaline synthetase (Gutierrez *et al.* 1991).

This confirms that cosmid pIBV3 isolated in Example 5.1 does indeed contain a portion of the structural gene for pristinamycin I synthase III described in Example 5.4, designated SnbD (SEQ ID nos. 13 and 14).

#### 8.7. 291-bp and 485-bp fragments (pVRC1104)

This example illustrates how it is possible to determine the open reading frames present within the 291-bp and 485-bp fragments sequenced from pVRC1104 as described in Examples 6 and 7.

The search for open frames for these two fragments was performed as above. An incomplete reading frame could be demonstrated in both cases over the whole length of the fragment.

5       The sequence obtained from the open frame identified on the 291 fragment isolated from the 1450-bp PstI fragment contains the internal sequence of the protein SnbE purified as described in Example 5.

10       Comparison of the product of the open frame identified on the 485-bp XhoI-SphI fragment isolated from pVRC1104 with the sequences of the Genpro bank reveals that it is homologous to peptide synthases, for example 34.7% homologous with *Bacillus* gramicidin S synthase II (Hori et al. 1991) and 36.2% with  
15    Acronium chrysogenum ( $\alpha$ -aminoadipyl)cysteinyvaline synthetase (Gutierrez et al. 1991).

      This confirms that cosmid pIBV3 isolated in Example 5.1 does indeed contain a portion of the structural gene for pristinamycin I synthase IV  
20    described in Example 5.5, designated SnbE (SEQ ID 15 and 16).

#### 8.8. 645-bp fragment (pVRC903)

      This example illustrates how it is possible to determine the open reading frames present within the  
25    645-bp fragment sequenced above from plasmid pVRC903 as described in Example 6.7.

      The search for open reading frames for the 645-bp fragment was performed as above. An incomplete

open reading frame could be demonstrated in this way. Its characteristics are as follows: this frame affords two possibilities for initiation of translation, a GTG at position 61 and a GTG at position 70 of the

5 sequenced portion (the ATG located at position 124 was not taken into account owing to the sequence homologies described later). Analysis of the probabilities of the presence of Shine-Dalgarno regions does not make it possible to distinguish which of these codons  
10 corresponds to the initiation. No stop codon was identified, which indicates that this open reading frame is not terminated. The gene identified in this way was referred to as papA, and the corresponding protein was referred to as protein PapA (SEQ ID no. 9).

15 Comparison of the product of the open reading frame identified in the 3.4-kb XhoI-XhoI fragment isolated from pVRC900 with sequences contained in the Genpro bank reveals that it is homologous to the II components of proteins of the p-aminobenzoate synthase  
20 and anthranilate synthase type, involved, respectively, in the synthesis of p-aminobenzoic acid (folic acid precursor) and in the synthesis of anthranilic acid (tryptophan precursor) of various microorganisms. It displays, in particular, a 48% homology with the  
25 protein TrpG of Azospirillum (Zimmer W., Aparicio C., and Elmerich c. Mol. Gen. Genet. (1991) 229:41-51) and a 47% homology with the protein PabA of Klebsiella pneumoniae (Kaplan J. B., Merkel W. K. and

Nichols B. P. J. Mol. Biol. (1985) 183:327-340). The proteins TrpG and PabA carry the glutaminase activity involved in the transamination of chorismic acid. The homologies demonstrated tend to show that the protein  
5 PapA might be involved as well in the activity of transamination of chorismic acid. Chorismic acid is proposed as a precursor of p-dimethylaminophenyl-alanine, a component of pristinamycins I, by analogy with the synthesis of chloramphenicol, an antibiotic  
10 deduced by Streptomyces (Sharka B., Westlake D. W. S. and Vining L. C. (1970) Chem. Zvesti 24, 66-72).

The role of the protein PapA will be shown subsequently (Example 9.3.) by analysis of mutants of the strain SP92 in the papA gene.

15 8.9. 1.5-kb BamHI-SstI fragment (PVRC1000)

This example illustrates how it is possible to determine the open reading frames present within the 1.5-kb BamHI-SstI fragment isolated above and sequenced as described in Examples 6.8 and 7.9.

20 The search for open reading frames for the sequenced region of 640 bp present in the 1.5-kb BamHI-SstI fragment was performed as described in Example  
8.1. A single complete open reading frame could be demonstrated in this way. No initiation and no  
25 termination of translation could be demonstrated, which indicates that the sequenced region of 640 bp is probably internal to a much larger reading frame, designated snaD (SEQ ID no. 8).

Comparison of the protein sequence encoded by the region of 640 bp with the protein sequences contained in the Genpro and NBRF banks reveals that this protein is 20-25% homologous to an internal  
5 portion of peptide synthases such as B. brevis gramicidin synthase I (Hori et al. 1989), B. brevis tyrocidin synthase I (Weckermann et al. 1988) and Acremonium chrysogenum ACV synthase (Gutierrez et al. (1991)).

10           These data indicate that the protein partially encoded by the region of 640 bp is probably a peptide synthase involved in the biosynthesis of the peptide portion of pristinamycins II: in effect, all the peptide synthases involved in the biosynthesis of  
15 pristinamycins I have already been identified in other regions of the S. pristinaespiralis chromosome, as is described in Examples 5.2, 5.3, 5.4 and 5.5.

#### 8.10. 694-bp fragment (pVRC509)

This example illustrates how it is possible  
20 to determine the open reading frames present within the 694-bp fragment sequenced above from pVRC509 as described in Examples 6 and 7.

..... The search for open reading frames for the 694-bp fragment was performed as above. An incomplete  
25 open reading frame could be demonstrated in this way. Its characteristics are as follows: this frame begins at position 210 of the sequenced portion. No stop codon was identified, which indicates that this open frame is

not terminated. Hence the molecular mass of the corresponding protein cannot be calculated and compared to the apparent molecular mass of 28,000 Da of the FMN reductase, estimated on SDS-PAGE as described in

- 5 Example 5.6. On the other hand, the NH<sub>2</sub>-terminal sequence of the protein identified in this way by analysis of the open reading frames of the sequence of 694-bp is identical to that NH<sub>2</sub>-terminal sequence of the proteins SnaC purified as described in Example 5.
- 10 Similarly, the two internal protein sequences of the FMN reductase described in 5.6 occur in the protein deduced from the sequenced portion. This confirms that the gene isolated from cosmid pIBV4 does indeed correspond to the protein FMN reductase described in
- 15 Example 5.6, designated SnaC (SEQ ID no. 7).

A study of the DNA fragments of S. pristinaespiralis strain SP92 carried by cosmids pIBV1 to pIBV2 demonstrated the presence of several genes involved in the biosynthesis of pristinamycins II and

20 pristinamycins I. The snaA, snaB and samS genes code for enzymes participating in the biosynthesis of pristinamycins II, pristinamycin IIA synthase and probable SAM synthase, and are grouped together

25 physically on a large DNA fragment cloned into plasmid pIBV1. Similarly, the snbA, snbR, papA and papM genes - which code for proteins participating in the biosynthesis of pristinamycins I, 3-hydroxypicolinic acid:AMP ligase (SnbA), the protein SnbR probably

responsible for the transport of pristinamycins I, the protein Papa involved in the biosynthesis of p-aminophenylalanine from chorismic acid, and p-aminophenylalanine (phenyl-N)-methyltransferase (PapM) - are grouped together on a large DNA fragment cloned into cosmid pIBV2. Similarly, the snaA and snaD genes on the one hand - which code for proteins participating in the biosynthesis of pristinamycins II, the protein SnaD probably being a peptide synthase - and the snbC, snbD and snbE genes on the other hand - which code for the 3 peptide synthases SnbC, SnbD and SnbE involved in the formation of the peptide chain of pristinamycin I from its 6 separate amino acids - are grouped together on a large DNA fragment cloned into cosmid pIVB3. These results confirm the hypothesis of the grouping together of the genes for the biosynthesis of pristinamycins II, and also of the genes for the biosynthesis of pristinamycins I, and afford the possibility of cloning the other genes involved in these biosyntheses, by chromosome walking, upstream and downstream of the regions studied.

Furthermore, it is possible by hybridization of the total DNA of the different strains producing streptogramins (see Table 1) with the snaA, snaB, snaC, snaD, snaS, snbA, snbR, snbC, snbD, snbE, papA and papM genes, or with the genes identified by chromosome walking, or with fragments of these genes, to isolate the genes corresponding to the same functions in the

other microorganisms producing streptogramins. This makes it possible, by the same approach as that envisaged for the pristinaamycins, to isolate all the genes involved in the biosynthesis of the different streptogramins.

EXAMPLE 9: Genetic study of DNA fragments by gene disruption

This example illustrates how it is possible to demonstrate the involvement of genes in the biosynthesis of streptogramins by constructing strains derived from a producing strain and mutated in these genes by disruption, and by analysing the phenotype of such mutants. This example shows, furthermore, how to obtain strains that are left producing only one or other of the A and B components of streptogramins, or producing A and B components with ratios different from those observed with the strain SP92.

9.1. Construction of a mutant of *S. pristinaespiralis* SP92 disrupted in the *snaA* gene

This example illustrates how it is possible, by disruption of the *snaA* gene, to construct a strain of *S. pristinaespiralis* SP92 which no longer produces pristinaamycin IIA and which produces, in contrast, pristinaamycin IIB.

This mutant was constructed for the purpose of confirming the functionality of the protein SnaA and of providing an intermediate of pristinaamycin II production capable of being modified subsequently.

Its construction was carried out using a suicide vector capable of replicating in E. coli only but carrying a resistance marker which is expressed in Streptomyces. This vector, pDH5, was developed by  
5 Hillemann et al. (1991).

#### 9.1.1. Construction of plasmid pVRC505

This example illustrates how it is possible to construct a plasmid which does not replicate in S. pristinaespiralis SP92 and which may be used to  
10 disrupt the snaA gene by single homologous recombination.

Plasmid pVRC505 was constructed to produce the SP92 chromosomal mutant disrupted in the snaA gene from plasmid pXL2045 described in Example 6.3.

15 The 6-kb BamHI fragment, cloned into pXL2045 (Figure 16), was cut with the restriction enzymes EcoRI and PstI. After separation of the fragments thereby generated by electrophoresis on 1 % agarose gel, a 0.7-kb fragment containing the 5' end of the snaA gene  
20 was isolated and purified by Geneclean (Bio101, La Jolla, California).

100 ng of vector pDH5 linearized by an EcoRI/PstI double digestion were ligated with 100 ng of the 0.7-kb fragment, as described in Example 3.3. A  
25 clone carrying the desired fragment was isolated after transformation of the strain TG1. The recombinant plasmid was designated pVRC505. Plasmid pVRC505 was prepared as described in Example 2.1. Its restriction

map is presented in Figure 25.

9.1.2. Isolation of the SP92 mutant disrupted in the snaA gene by homologous recombination

This example illustrates how the mutant of  
5 S. pristinaespiralis SP92 disrupted in the snaA gene was constructed.

This mutant was isolated by transformation of the strain SP92 with the suicide plasmid pVRC505.

The preparation of the protoplasts and their  
10 transformation were carried out as described in D. Hopwood et al. (1985).

The strain SP92 was cultured in YEME medium, 34 % sucrose, 5 mM MgCl<sub>2</sub>, 0.25 % glycine for 40 hours at 30°C. The mycelium was converted to protoplasts in the  
15 presence of lysozyme, and 5 x 1 µg of pVRC505 were used for the transformation (by the method employing PEG) of the protoplasts. After overnight regeneration of the protoplasts on R2YE medium (D. Hopwood et al. 1985), the recombinants were selected by overlaying 3 ml of  
20 SNA medium (D. Hopwood et al. 1985) containing 2.6 µg/ml of thiostrepton.

Of the 5 transformations carried out, 3 thiostrepton-resistant clones were isolated. This gives a recombinant efficiency of less than 1 per µg of DNA.  
25 These recombinants result from integration by single homologous recombination between the snaA gene carried by the chromosome of the strain SP92 and the 0.7-kb fragment of the suicide plasmid pVRC505. The small size

of the fragment inserted into pVRC505, 0.7-kb, explains the low recombination efficiency.

The spores of the recombinants were isolated by plating out and growth on R2YE medium supplemented with 400 µg/ml of thiostrepton, and plated out again on the same medium to obtain isolated colonies.

In order to verify the position of integration of plasmid pVRC505, various Southern blots of the total DNA of several recombinant clones, which was digested with the appropriate restriction enzymes, were produced and hybridized with the vector pDH5 and the 0.7-kb fragment, used successively as probes after labelling by random priming (Random Primed DNA labeling kit, Boehringer Mannheim, France) with [ $\alpha$ - $^{32}$ P]-dCTP, as described in Maniatis *et al.* (1989). The hybridization results show the appearance in the genome of the recombinant clones of an additional EcoRI-PstI band, of the size of the vector pDH5 and which hybridizes with the latter, as well as of an additional EcoRI-EcoRI band which hybridizes with both the 2 probes. One of these mutants was designated SP92::pVRC505. This mutant corresponds well to the integration of plasmid pVRC505 in the snaA gene by single homologous recombination.

9.1.3. Production of pristinamycins by the mutant SP92::pVRC505

This example illustrates how it is determined that the mutant of S. pristinaespiralis SP92 disrupted in the snaA gene by integration of plasmid pVRC505 no

longer produces pristinamycin IIA while continuing to produce pristinamycin IIB.

The mutant SP92::pVRC505, as well as the strain SP92 as control strain, were culture in liquid production medium. Fermentation was carried out as follows: 0.5 ml of a suspension of spores of the strains mentioned are added under sterile conditions to 40 ml of inoculum medium in a 300-ml Erlenmeyer. The inoculum medium consists of 10 g/l of corn steep, 15 g/l of sucrose, 10 g/l of  $(\text{NH}_4)_2\text{SO}_4$ , 1 g/l of  $\text{K}_2\text{HPO}_4$ , 3 g/l of NaCl, 0.2 g/l of  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  and 1.25 g/l of  $\text{CaCO}_3$ . The pH is adjusted to 6.9 with sodium hydroxide before the introduction of calcium carbonate. The Erlenmeyers are stirred for 44 hours at 27°C on a rotary stirrer at a speed of 325 rpm. 2.5 ml of the above culture when 44 hours old are added under sterile conditions to 30 ml of production medium in a 300-ml Erlenmeyer. The production medium consists of 25 g/l of soya flour, 7.5 g/l of starch, 22.5 g/l of glucose, 3.5 g/l of feeding yeast, 0.5 g/l of zinc sulphate and 6 g/l of calcium carbonate. The pH is adjusted to 6.0 with hydrochloric acid before the introduction of calcium carbonate. The Erlenmeyers are stirred for 24, 28 and 32 hours at 27°C. At each time, 10 g of must are weighed into a smooth Erlenmeyer, and 20 ml of mobile phase composed of 62.5 % of acetonitrile and 37.5 % of 0.1 M  $\text{KH}_2\text{PO}_4$  solution (adjusted to pH 3.0 with  $\text{H}_3\text{PO}_4$ ), and which enables the pristinamycins to be extracted,

are added to this. After stirring on a stirrer (325 rpm) for 20 min at room temperature, the whole is filtered through filter paper and the pristinamycins are assayed by HPLC as described in Example 5.1.1.A.

5           The results showed that, under the fermentation conditions implemented, the mutant SP92::pVRC505 produced an amount of pristinamycin I equivalent to that of the SP92 control, this being the case for all 3 times tested. In contrast, whereas the control produced approximately 70 % of pristinamycin IIA and 30 % of pristinamycin IIB at 24, 28 and 10 32 hours of fermentation, the mutant SP92::pVRC505 produced 100 % of pristinamycin IIB for these same times, in amounts equivalent to the sum of 15 pristinamycin IIA + pristinamycin IIB produced by the strain SP92. Hence the mutant is indeed blocked in a step of biosynthesis of pristinamycin II which corresponds to the oxidation of the 2,3 bond of the D-proline of the intermediate pristinamycin IIB. This 20 mutant hence accumulates pristinamycin IIB. This shows well the functional involvement of SnaA in the conversion of pristinamycin IIB to pristinamycin IIA.

— This example shows that it is possible, starting from cloned genes for biosynthesis, to 25 construct strains that are mutated in the steps of biosynthesis of pristinamycin. This was shown for pristinamycin II, but the same results may be obtained for pristinamycins I and, by extension, for the

different components of streptogramins. Strains producing different intermediates may thus be obtained. These strains may be used to produce novel molecules by chemical, biochemical, enzymatic, and the like, modification(s) of the said intermediates. A block in an early step of the biosynthesis pathway of one or other of the components of streptogramins may also lead to mutated strains that are left producing only one or other of the components.

## 9.2. Construction of a mutant of *S.*

### *pristinaespiralis* SP92 disrupted in the *samS* gene

This example illustrates how it is possible, by disruption of the *samS* gene, to construct a strain of *S. pristinaespiralis* SP92 which produces 35 % less PIA and 10 times as much PIB (the chemical structures are shown in Figure 2) relative to the wild-type SP92 strain. This mutant was constructed for the purpose of confirming the presumed SAM synthase function for the protein encoded by the *samS* gene, and for obtaining a strain that synthesizes more PIB than the wild-type SP92 strain.

#### 9.2.1. Construction of plasmid pVRC702

From plasmid pXL2045 (described in Example 6.3), the 3.2-kb *Bam*H1-*Eco*R1 fragment was isolated by enzymatic cleavage and purified after electrophoresis on 1 % agarose gel by the GeneClean kit method (see Example 6.8). This fragment carries *snaB* gene as well as the *samS* gene (Figure 16). This fragment is then

cloned into a plasmid pUC18 in the following manner:  
50 ng of pUC18 were linearized by double digestion  
using the enzymes EcoRI and BamHI, and then ligated in  
the presence of T $\phi$  DNA ligase (Biolabs) with 300 ng of  
5 the 3.2-kb BamHI-EcoRI fragment. After transformation  
of competent cells of E. coli strain TG1 with this  
ligation mixture, a recombinant clone possessing  
plasmid pUC18 with the 3.2-kb insert could be isolated,  
and this was designated pVRC701 (Figure 26).

10 Plasmid pVRC702 is derived from plasmid  
pVRC701 by the introduction between the two SstI sites  
located in the middle of the samS gene (Figure 27) of a  
cassette carrying the amR gene coding for resistance to  
amramycin and genitacin. To this end, a 2.2-kb BamHI-  
15 BamHI fragment carrying the QamR cassette was first  
isolated by BamHI digestion of plasmid pHP45QamR (given  
by J. L. Pernodet, Laboratoire de Génétique d'Orsay)  
using the same technique as above. 200 ng of this  
fragment were then ligated with 50 ng of plasmid  
20 pUC1318 (Kay and McPherson, 1987) linearized with the  
enzyme BamHI, and this ligation mixture was introduced  
into competent E. coli TG1 cells. From the recombinant  
zone possessing plasmid pUC1318 containing the QamR  
cassette, 50 ng of a 2.2-kb SstI-SstI fragment  
25 containing the QamR cassette could be reisolated by  
partial cleavage using the enzyme SstI, and this  
fragment was ligated with 30 ng of plasmid pVRC701 cut  
with SstI (Figure 26) to give, after transformation of

competent E. coli TG1 cells, plasmid pVRC702, the structure of which is detailed in Figure 27.

Plasmid pVRC702 thereby obtained was prepared in large amounts according to the method described  
5 above in Example 2.1.

9.2.2. Construction of the strain having the samS:: $\Delta$ amR chromosomal gene

This strain was obtained by transformation of S. pristinaespiralis protoplasts with 1  $\mu$ g of the  
10 suicide plasmid pVRC702 which is incapable of replicating in a Streptomyces cell. The protocols for preparation of the protoplasts and for transformation are the same as above (Example 9.1). The only  
15 modifications made with respect to Example 10.1 relate to the selection antibiotic. In the present case, the recombinant protoplasts after regeneration for 18 hours at 30°C on R2YE medium are selected in the presence of 50  $\mu$ g/ml final of gentamicin (Sigma Chemical Co.). Thus, an overlayer composed of 3 ml of SNA containing  
20 383  $\mu$ g/ml of gentamicin is added to each dish of R2YE.

In this way, it was possible to isolate 500 gentamicin-resistant recombinant clones, which may result either from an integration of plasmid pVRC702 into the chromosome following a single homologous  
25 recombination between chromosomal and plasmid samS genes (in the case of single crossing-over), or from an exchange between the chromosomal samS gene and the plasmid samS:: $\Delta$ amR plasmid gene following a double

homologous recombination event (in the case of double crossing-over). In these two cases in point, the QamR cassette becomes transferred onto the chromosome of the strain, and endows it with an amR resistance which is  
5 stable over generations.

The recombinant clones were isolated by plating out and growth on HT7 medium containing 50 µg/ml final of geneticin, and then analyzed by the colony hybridization technique. Hybridization of the  
10 clones with a first probe obtained as described in Example 9.1 from the 2.7-kb BamHI-EcoRI fragment originating from pVRC702 and corresponding to pUC18, as well as with a second probe corresponding to the 2.2-kb BamHI fragment carrying the QamR cassette, enable the  
15 cases of single crossing-over (hybridizing with both probes) to be distinguished from the cases of double crossing-over (hybridizing only with the second probe). The 3 clones resulting from a double crossing-over thereby selected were purified by plating out and  
20 growth on YVD medium containing 50 mg/ml final of geneticin, and stocks of spores were obtained.

In order to verify the genomic structure of the 3 double recombinants, various Southern blots of the chromosomal DNA of these clones digested with the  
25 enzymes EcoRI and BamHI were produced and hybridized with the following three probes: the probe corresponding to the QamR cassette obtained from the 2.2-kb BamHI fragment of pVRC702, the probe

corresponding to pUC18 obtained from the 2.7-kb BamHI-EcoRI fragment of pVRC701, and lastly a probe obtained from the 1.3-kb EcoRI-SstI fragment of pVRC701 carrying the snaB gene and the beginning of samS. These hybridizations enabled it to be verified that the three clones tested did indeed result from a double homologous recombination event permitting replacement of the intact chromosomal samS gene by the mutated samS gene interrupted by the QamR cassette.

One of these three mutant clones was designated SP92 samS::QamR.

#### 9.2.3. Production of pristinamycins by the mutant strain samS::QamR

This example illustrates how it is determined that the mutant SP92 samS::QamR having the disrupted samS gene produces 35 % less pristinamycin IA and 10-fold more pristinamycin IB than the wild-type SP92 strain.

The mutant SP92 samS::QamR as well as the control SP92 strain were cultured in liquid production medium, and their productions of pristinamycin II and pristinamycin I were assayed as described in Example 9.1.

The results showed that, under the fermentation conditions implemented, the mutant SP92 samS::QamR produces an amount of pristinamycins II equivalent to that of the SP92 control for all three times tested. In contrast, the mutant SP92 samS::QamR

produces approximately 35 % less pristinamycin IA and 10-fold more pristinamycin IB than the control strain at all three times tested. The IB form of pristinamycins thus represents 20 % of the collective total type I pristinamycins produced by the mutant SP92 samS::QamR, whereas the control strain synthesizes only of the order of 1 % of PIB. The IB form of pristinamycins differs from the IA form in that the fifth residue is p-methylaminophenylalanine, instead of p-dimethylaminophenylalanine for pristinamycin IA. The fact that the mutant SP92 samS::QamR produces more pristinamycin IB and less pristinamycin IA shows that disruption of the samS gene causes a decrease in the degree of methylation of the fifth residue of pristinamycins I, and hence that the samS gene is probably involved in the biosynthesis of the methyl donor, SAM, that is to say that it codes for a SAM synthase.

### 9.3 Construction of a mutant of S.

pristinaespiralis SP92 disrupted in the papA gene

This example illustrates how it is possible, by disruption of the papA gene, to construct a strain of S. pristinaespiralis SP92 which no longer produces PI. This mutant is constructed for the purpose of confirming the functionality of the PapA protein. Its construction was carried out using the suicide vector pDH5 described in Example 9.1.

#### 9.3.1. Construction of plasmid pVRC508

This example illustrates how it is possible to construct a plasmid which does not replicate in S. pristinaespiralis SP92 and which may be used to disrupt the papA gene by single homologous recombination.

Plasmid pVRC508 was constructed to produce the SP92 chromosomal mutant disrupted in the papA gene from plasmid pVRC903 described in Example 7.7.

In Example 7.7, the cloning of the 1.4-kb PvuII-EcoRI fragment into M13mp18 from plasmid pVRC903 for the purpose of sequencing the papA gene was described (this fragment corresponds to the 1.4-kb PvuII-XhoI fragment present in the vector pVRC900, Figure 23).

This construction in M13mp18 was digested with the restriction enzyme HindIII and EcoRI. After separation of the vector M13mp18 and the 1.4-kb fragment containing a portion of the papA gene on 0.8 % agarose gel, the latter fragment was isolated and purified by Geneclean (Bio101, La Jolla, California). The localization of the fragment in the papA gene is presented in Figure 23.

100 ng of vector pDH5 linearized by a double digestion with the restriction enzymes HindIII and EcoRI were ligated with 200 ng of the 1.4-kb fragment as described in Example 3.3. A clone carrying the desired fragment was isolated after transformation of the strain TG1. The recombinant plasmid was designated

pVRC508. Plasmid pVRC508 was prepared as described in Example 2.1. Its restriction map is presented in Figure 28.

9.3.2. Isolation of the SP92 mutant disrupted  
5 in the papA gene by homologous recombination

This example illustrates how the mutant of  
S. pristinaespiralis SP92 disrupted in the papA gene  
was constructed. This mutant was isolated by  
transformation of the strain SP92 with the suicide  
10 plasmid pVRC508. The preparation of the protoplasts and  
their transformation were carried out as described in  
Example 9.1. After transformation of protoplasts of the  
strain SP92, the recombinants were selected by  
overlaying 3 ml of SNA medium containing 2.6 mg/ml of  
15 thiostrepton. Of the 5 transformations carried out with  
5 times 1 µg of plasmid pVRC508, ten thiostrepton-  
resistant clones were isolated. This gives a  
recombinant efficiency of approximately 2 per µg of  
DNA. These recombinants result from integration by  
20 single homologous recombination between the papA gene  
carried by the chromosome of the strain SP92 and the  
1.4-kb fragment of the suicide plasmid pVRC508.

The spores of the recombinants were isolated  
by plating out and growth on R2YE medium containing  
25 400 µg/ml of thiostrepton, and plated out again on the  
same medium to obtain isolated colonies.

In order to verify the position of  
integration of plasmid pVRC508, various Southern blots

of the total DNA of several recombinant clones, purified as described above, were produced and hybridized with the vector pDH5 and the 1.4-kb fragment, used successively as probes after labelling  
5 by random priming with [ $\alpha$ - $^{32}$ P]dCTP as described in Maniatis et al. (1989). The hybridization results show the disappearance from the genome of the recombinant clones digested with the restriction enzyme EcoRI (site flanking the 1.4-kb fragment) of the 6.8-kb EcoRI band,  
10 and the appearance of two additional bands relative to the control SP92 strain, one of 2.4 kb hybridizing with the 1.4-kb fragment, and the other of 10.5 kb hybridizing both with pDH5 and with the 1.4-kb fragment. Digestion of the recombinant clones with the  
15 restriction enzyme PstI shows the appearance of two additional bands relative to the control SP92 strain, one of 1.0 kb hybridizing with the 1.4-kb fragment, and the other of 5.1 kb hybridizing both with pDH5 and with the 1.4-kb fragment. One of these mutants was  
20 designated SP92::pVRC508.

#### 9.3.3. Production of pristinamycins by the mutant SP92::pVRC508

— This example illustrates how it is determined that the mutant of S. pristinaespiralis SP92 disrupted  
25 in the papA gene by integration of plasmid pVRC508 no longer produces PI.

The mutant SP92::pVRC508, as well as the strain SP92 as control strain, were cultured in liquid

production medium. The fermentation and also the assay of pristinamycins I and II were carried out as described in Example 9.1.

The results showed that, under the  
5 fermentation conditions implemented, whereas the control SP92 strain produced a standard amount of pristinamycins I, no trace of type I pristinamycins was detected in the fermentation must of the mutant SP92::pVRC508. Moreover, the production of  
10 pristinamycins II by the mutant SP92::pVRC508 is equivalent to that of the SP92 control. The mutant SP92::pVRC508 is left producing only pristinamycins II. These results show clearly that the papA gene codes for a protein involved in the biosynthesis of  
15 pristinamycins I.

To check the absence of polarity of the disruption carried out in the mutant SP92::pVRC508, the latter was fermented in the presence p-dimethylamino-phenylalanine. The mutant SP92::pVRC508 was fermented  
20 as described above, with the addition, at 17 hours of fermentation, of 100 mg/l of p-dimethylaminophenylalanine. Under these conditions of complementation, the mutant SP92::pVRC508 produces an amount of pristinamycins I equivalent to that produced by the  
25 strain SP92. The production of pristinamycins II is equivalent in both strains. This enables us to conclude that the mutant SP92::pVRC508 does not produce pristinamycins I because it is indeed disrupted in a

gene that participates in the biosynthesis of p-dimethylaminophenylalanine (the papA gene).

Complementation of this mutant with p-dimethylamino-phenylalanine restores its capacity to produce

5   pristinamycins I, proving that the mutation has no polar effect on the synthesis of other pristinamycin I precursors or on the condensation of these precursors.

          This example shows that it is possible, starting from cloned genes for biosynthesis, to  
10   construct strains that are mutated in the steps of biosynthesis of pristinamycins, and especially pristinamycins I. This example also shows that it is possible, by this approach, to construct strains of S. pristinaespiralis specifically producing  
15   pristinamycins II and, by extension, strains specifically producing pristinamycins I. This same approach could also be used for other strains of actinomycetes producing streptogramins.

#### 9.4. Construction of mutant of

20   S. pristinaespiralis SP92 disrupted in the snbA gene

          This example illustrates how it is possible, by disruption of the snbA gene, to construct a strain of S. pristinaespiralis SP92 which no longer produces pristinamycins I. This mutant was constructed for the  
25   purpose of confirming the functionality of the SnbA protein. Its construction was carried out using the suicide vector pDH5 described in Example 9.1.

##### 9.4.1. Construction of plasmid pVRC404

This example illustrates how it is possible to construct a plasmid which no longer replicates in S. pristinaespiralis SP92 and which may be used to disrupt the snbA gene by single homologous recombination.

Plasmid pVRC404 was constructed from plasmid pVRC402 described in Example 6.2, to produce the SP92 chromosomal mutant disrupted in the snbA gene. Plasmid pVRC402 was digested with the restriction enzyme XhoI and HindIII. After separation of the fragments thereby generated by electrophoresis on 0.8 % agarose gel, a 1170-bp fragment containing an internal portion of the snbA gene was isolated and purified by Geneclean (Bio101, La Jolla, California). The localization of the fragment in the snbA gene is presented in Figure 15A.

100 ng of vector pDH5 linearized by an SmaI digestion were ligated with 200 ng of the 1173-bp fragment as described in Example 3.3. A clone carrying the desired fragment was isolated after transformation of the strain TG1. The recombinant plasmid was designated pVRC404. Plasmid pVRC404 was prepared as described in Example 2.1. Its restriction map is presented in Figure 29.

9.4.2. Isolation of the SP92 mutant disrupted in the snbA gene by homologous recombination

This example illustrates how the mutant of S. pristinaespiralis SP92 disrupted in the snbA gene was constructed.

This mutant was isolated by transformation of the strain SP92 with the suicide plasmid pVRC404. The preparation of the protoplasts and their transformation were carried out as described in Example 9.1. After transformation of protoplasts of the strain SP92, the recombinants were selected by overlaying 3 ml of SNA medium containing 2.6 mg/ml of thiostrepton. Of the 5 transformations carried out with 5 times 1 µg of plasmid pVRC404, about thirty thiostrepton-resistant clones were isolated. This gives a recombinant efficiency of approximately 5 per µg DNA. These recombinants result from integration by single homologous recombination between the snbA gene carried by the chromosome of strain SP92 and the 1170-bp fragment of the suicide plasmid pVRC404. The spores of the recombinants were isolated by plating out and growth on R2YE medium + 400 mg/ml of thiostrepton, and plated out again on the same medium to obtain isolated colonies. In order to verify the position of integration of plasmid pVRC404, various Southern blots of the total DNA of several recombinant clones, purified as described above, were produced and hybridized with the vector pDH5 and the 1170-kb fragment, used successively as probes after labelling by random priming with [ $\alpha$ -<sup>32</sup>P]dCTP as described in Maniatis et al. (1989). The hybridization results show the appearance in the genome of the recombinant clones digested with the restriction enzymes XhoI and HindIII

of an additional 4.7-kb XhoI-HindIII band relative to the control SP92 strain (vector pDH5 + 1.17 kb), hybridizing both with pDH5 and with the 1170-bp fragment. Digestion of the recombinant clones with the restriction enzyme PflMI (sites flanking the 1170-bp XhoI-HindIII fragment) shows the disappearance of the 3.1-kb PflMI-PflMI band and the appearance of a band at 8.8 kb hybridizing with both probes. These results indicate that the genomic structure of the clones analysed is indeed that expected after a homologous recombination event between pVRC404 and the chromosomal snbA gene. One of these mutants was designated SP92::pVRC404.

#### 9.4.3. Production of pristinamycins by the mutant SP92::VRC404

This example illustrates how it is determined that the mutant of S. pristinaespiralis SP92 disrupted in the snbA gene by integration of plasmid pVRC404 no longer produces PI.

The mutant SP92::pVRC404, as well as the strains SP92 as control strain, were cultured in liquid production medium. The fermentation and also the assay of pristinamycins I and II were carried out as described in Example 9.1. The results showed that, under the fermentation conditions implemented, whereas the control SP92 strain produces a standard amount of pristinamycins I, no trace of pristinamycins I was detected in the fermentation must of the mutant

SP92::pVRC404. Moreover, the production of pristinamycins II by the mutant SP92::pVRC404 is equivalent to that of the SP92 control. The mutant SP92::pVRC404 is left producing only pristinamycins II.

5 This shows clearly that the snbA gene codes for a protein SnbA involved in the biosynthesis of pristinamycins I, as had been shown during the purification in Example 5.2.

10 This example shows, as in the preceding example, that it is possible, starting from cloned genes for biosynthesis, to construct strains that are mutated in the steps of biosynthesis of pristinamycins, and especially pristinamycins I. This example also shows that is possible, by this approach, to produce  
15 strains of S. pristinaespiralis specifically producing pristinamycins II and, by extension, strains specifically producing pristinamycins I, as described in the following example: 9.5. This same approach could also be used for other strains of actinomycetes  
20 producing streptogramins.

9.5. Construction of a mutant of  
S. pristinaespiralis SP92 disrupted in the *snbD* gene  
probably coding for a peptide synthase involved in the  
biosynthesis of pristinamycins II

25 This example illustrates how it is possible, by disruption of the snbD gene probably coding for a peptide synthase involved in the biosynthesis of pristinamycins II, to construct a strain of

S. pristinaespiralis SP92 which no longer produces pristinamycins II.

This mutant was constructed for the purpose of confirming the functionality of the snaD gene, and  
5 of obtaining a strain derived from SP92 left synthesizing only pristinamycins I.

Its construction was carried out using plasmid pVRC1000 described in Example 6.8, derived from the suicide vector pDH5, capable of replicating in  
10 E. coli only and carrying a resistance marker which is expressed in Streptomyces (see Example 9.1).

#### 9.5.1 Construction of plasmid pVRC1000

This example illustrates how it is possible to construct a plasmid which does not replicate in  
15 S. pristinaespiralis SP92 and which may be used to disrupt the snaD gene by single homologous recombination. The construction of plasmid pVRC1000 carrying a portion of the snaD gene is described in Example 6.8.

20 9.5.2. Isolation of the SP92 mutant disrupted in the snaD gene by homologous recombination

This example illustrates how the mutant of S. pristinaespiralis SP92 disrupted in the snaD gene was constructed. This mutant was isolated by  
25 transformation of the strain SP92 with the suicide plasmid pVRC1000. The preparation of the protoplasts and their transformation were carried out as described in Example 9.1. Of the 5 transformations carried out

with 1 mg of pVRC1000, approximately 1500 thiostrepton-resistant clones were isolated. This gives a recombinant efficiency of approximately 375 per  $\mu$ g of DNA. These recombinants result from integration by  
5 single homologous recombination between the snad gene carried by the chromosome of the strain SP92 and the 1.5-kb BamHI-SstI fragment of the suicide plasmid pVRC1000. About twenty recombinants were subcultured on R2YE medium containing 400  $\mu$ g/ml of thiostrepton, and  
10 the spores of these recombinants were isolated by plating out again and growth on R2YE medium containing 400  $\mu$ g/ml of thiostrepton.

In order to verify the position of integration of plasmid pVRC1000, various Southern blots  
15 of the total DNA of 7 recombinant clones, purified as described above, were produced and hybridized with the vector pDH5 and the 1.5-kb BamHI-SstI fragment contained in pVRC1000, used successively as probes after labelling with [ $\alpha$ - $^{32}$ P]dCTP as described in Example  
20 9.1. The hybridization results show the appearance in the genome of the 7 recombinant clones of a 13.8-kb EcoRI band and an approximately 17-kb BglII band hybridizing with both probes, as well as a 3.7-kb EcoRI band hybridizing with the 1.2-kb BamHI-SstI probe. One  
25 of these mutants was designated SP92::pVRC1000 and corresponds well to the integration of plasmid pVRC1000 in the snad gene by single homologous recombination.

9.5.3. Production of pristinamycins by the mutant SP92::pVRC1000

This example illustrates how it is determined that the mutant of S. pristinaespiralis SP922 disrupted in the snaD gene by integration of plasmid pVRC1000 no longer produces pristinamycins II, but only pristinamycins I. The mutant SP92::pVRC1000, as well as the control SP92 strain, were cultured in liquid production medium, and their productions of pristinamycins II and I were assayed as described in Example 9.1.

The results showed that, under the fermentation conditions implemented and for all three times tested, the mutant SP92::pVRC1000 produces 0 mg/l of pristinamycins II and an amount of pristinamycins I equivalent to that of the SP92 control. Hence this mutant is indeed blocked in a step of biosynthesis of pristinamycins II, which shows that the snaD gene codes for an enzyme involved in the biosynthesis of pristinamycins II, and very probably for a peptide synthase.

This example shows, as in the preceding example, that it is possible, starting from cloned genes for biosynthesis, to construct strains that are mutated in the steps of biosynthesis of pristinamycins, and especially pristinamycins II. This example also shows that it is possible, by this approach, to produce strains of S. pristinaespiralis specifically producing

pristinamycins I and, by extension, strains specifically producing pristinamycins II. This same approach could also be used for other strains of actinomycetes producing streptogramins.

5           EXAMPLE 10: Complementation of a non-producing mutant of the strain SP92

          This example shows how it is possible to express genes for the biosynthesis of pristinamycins. This expression was implemented more especially for the  
10   snaA and snaB genes carried by cosmid pIBV1 in a mutant strain derived from SP92: SP120. This mutant does not produce pristinamycin IIA. It accumulates the last intermediate of the biosynthesis pathway of pristinamycin II: pristinamycin IIB.

15           10.1 Cloning of the snaA and snaB genes into the shuttle vector pIJ903

          This example illustrates how a subfragment of cosmid pIVB1 containing the snaA and snaB genes was cloned into a vector capable of replicating both in  
20   E. coli and in Streptomyces.

          The vector pIJ903 (Lydiate D. J. et al., 1985) is a low copy number (1 to 3 per cell) shuttle vector capable of replicating both in E. coli as a result of its origin of replication of pBR322, and in  
25   Streptomyces as a result of its origin of replication of SCP2'. The ampicillin resistance gene permits selection in E. coli, and the thiostrepton resistance gene permits selection in Streptomyces.

Cosmid pIBV1 was digested with the restriction enzyme SstI. A large 7.6-kb DNA fragment carrying the snaA and snaB genes was isolated by electrophoresis on 0.8 % agarose gel and electroeluted.

5 500 ng of this fragment were ligated with 100 ng of the vector pUC1813 (Kay and McPherson, 1987) linearized with SstI. After transformation of E. coli strain DH5 $\alpha$  (supE44 AlacU169 (f80lacZAM15) hsdR17 recA1 endA1 gyrA96 thi-1 relA1), and selection of the transformants  
10 on solid LB containing 150  $\mu$ g/ml of ampicillin and 20  $\mu$ g/ml of X-gal, a clone carrying the 7.6-kb fragment was isolated. The plasmid was designated pVRC506. A preparation of this recombinant plasmid was carried out as described in Example 2.1.

15 Cloning into the vector pIJ903 was carried out at the HindIII site. Plasmid pVRC506 was cut with HindIII, and 7.6-kb fragment carrying the snaA and snaB genes was isolated by electrophoresis on 0.8 % agarose gel and electroeluted. 500 ng of this fragment were  
20 ligated with 500 ng of the vector pIJ903 linearized with HindIII. After transformation of E. coli strain DH5 $\alpha$  and selection of the transformants on solid LB containing 150  $\mu$ g/ml of ampicillin, a clone carrying the 7.6-kb fragment was isolated. The plasmid was  
25 designated pVRC507. A preparation of this recombinant plasmid was carried out as described in Example 2.1. Its map is presented in Figure 30.

#### 10.2. Expression of the snaA and snaB genes

in the mutant SP120

This example illustrates how it is possible to produce the proteins SnaA and SnaB in S. pristinaespiralis SP92 by introducing a plasmid carrying the corresponding structural genes into this strain. Expression of the snaA and snaB genes was carried out after transformation of the mutant strain SP120 with 500 ng of plasmid pVRC507. Transformation of the protoplasts of SP120 and selection of the transformants with thiostrepton were carried out as described in Example 9.1.2.

Many transformants were obtained in this way, and 3 of them were chosen for the tests of production in a liquid medium. The strain SP120 carrying plasmid pIJ903 was chosen as control. The fermentations and also the extraction of the biosynthesis products were carried out as described in Example 9.1.3.

The results showed that, under the fermentation conditions implemented, whereas the control (SP120 carrying plasmid pIJ903) produced 100 % of P IIB and 0 % of P IIA at 24, 28 and 32 hours of fermentation, the 3 clones of the strain SP120 transformed with plasmid pVRC507 produced, for these same times, approximately 85 to 80 % of pristinamycin IIB and 15 to 20 % of pristinamycin IIA, the sum of which is equivalent in amount to the pristinamycin IIB production of the control strain (SP120 carrying plasmid pIJ903). The clones carrying pVRC507 were

indeed partially complemented for the step of biosynthesis of pristinamycins II corresponding to the oxidation of the 2,3 bond of the D-proline of the intermediate pristinamycin IIB. This was confirmed by enzymatic assay of pristinamycin IIA synthase activity, as described in Example 5.1.1.A, for the strains SP120 carrying pVRC507 and SP120 carrying pIJ903. Whereas the control strain SP120 carrying pIJ903 displays no pristinamycin IIA synthase activity, the strain SP120 carrying pVRC507 displays PIIA synthase activity.

This example shows that it is possible to express genes for the biosynthesis of streptogramins. This expression was studied more especially for the genes coding for pristinamycin IIA synthase, but the other genes for the biosynthesis of pristinamycins II and pristinamycins I, as well as those involved in the biosynthesis of the components of the different streptogramins, may be expressed in this way. This expression may be carried out in mutant strains as is the case in Example 10, but also in producing strains in order to increase the levels of streptogramin production. The expression may be modified by cloning the genes into a vector having a different copy number (low or high) or into an integrative vector, by deregulation of these genes, by cloning these genes under a homologous or heterologous promoter (strong or specifically regulated promoter). Expression of the different genes for the biosynthesis of streptogramins

may also be carried out in heterologous strains using appropriate expression vectors in order to produce hybrid antibiotics.

5     **EXAMPLE 11: Expression of the papM gene of S. pristinaespiralis in E. coli**

This example illustrates how it is possible to express an S. pristinaespiralis gene in E. coli so as to be able to identify, purify and study the protein encoded by this gene.

10     **11.1. Construction of plasmid pVRC706**

Expression of the papM gene in E. coli is obtained by placing this gene downstream of the promoter and ribosomes binding site of the lacZ gene of E. coli. The 1.7-kb MluI-StuI fragment was isolated from plasmid pVRC409 described in Example 7.8, and then cloned into plasmid pMTL23 (Chambers et al. 1988) cut at the BamHI site subsequently filled in using the Klenow enzyme (Maniatis et al. 1989) and at the MluI site, to give plasmid pVRC706 shown in Figure 31.

20     Cloning at the MluI site enables an in-frame fusion to be obtained between the first 32 amino acids of  $\beta$ -galactosidase encoded by the lacZ gene of plasmid pMTL23, and the last eleven amino acids of the gene located immediately upstream of papM, thereby making it

25     possible to preserve the translational coupling which appears to exist between the papM gene and this upstream gene in the light of the nucleotide sequence given in Example 7.8. Thus, the expression of the

hybrid gene between lacZ and the gene upstream of papM and that of the papM gene is under the control of the expression signals of the lacZ gene.

5     11.2 Expression in E. coli strain DH5a of the product of the papM gene

Plasmids pVRC706 and pMTL23 were introduced by transformation into E. coli strain DH5 $\alpha$ , and the expression of their genes was studied under conditions where the promoter of lacZ gene is induced as already described (Maniatis et al. 1989). The E. coli strains carrying plasmid pVRC706 or the control plasmid pMTL23 were cultured in 500 ml of LB rich medium containing 100 mg/ml of ampicillin and 1 mM IPTG, permitting induction of the promoter of the lacZ gene. These cultures are sampled when they have reached an optical density at 600 nm in the region of 1, and the protein extracts are prepared as described below.

15     11.3. Assay of the activity of the product of the papM gene expressed in E. coli

20     The activity corresponding to the protein encoded by the papM gene is assayed on the two extracts prepared from E. coli cultures carrying plasmid pVRC706 or plasmid pMTL23 (Example 5.7). It was shown that the extract prepared from the strain E. coli::pVRC706 catalyses the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine with an activity of 235 unit/mg, whereas this activity is absent in the extracts of the control strain E. coli::pMTL23 (see

Example 5.7.1.C). These results indicate that it is possible to express the papM gene of S. pristinae-spiralis in E. coli, and that the corresponding protein is indeed the enzyme catalysing the methylation of p-aminophenylalanine to p-dimethylaminophenylalanine. This example shows that it is possible to express genes for the biosynthesis of streptogramins in heterologous strains (such as E. coli, but also in other microorganisms) using appropriate expression vectors in order to produce precursors of antibiotics or even natural or hybrid antibiotics.

EXAMPLE 12: Demonstration of the homology of genes involved in the biosynthesis of streptogramins in different Streptomyces

This example illustrates how it is possible to demonstrate, by hybridization with total DNAs, the homology existing between different genes involved in the biosynthesis of streptogramins in different strains of Streptomyces producing streptogramins.

#### 12.1. Extraction of total DNA of different Streptomyces producing streptogramins

This example illustrates how the DNA of different strains producing streptogramins was purified. These strains of Streptomyces were chosen from those described in Table 1:

Streptomyces loidensis

Streptomyces olivaceus

Streptomyces ostreogriseus

Streptomyces virginiae

A strain not producing streptogramins:

5     Streptomyces hygroscopicus, was chosen as negative control.

The extractions of the different total DNAs were carried out from cultures in YEME medium, as described in Example 1.

10     12.2. Hybridization of total DNAs of strains producing streptogramins with DNA fragments containing genes involved in the biosynthesis of pristinamycins and isolated from S. pristinaespiralis strain SP92

15     This example illustrates how it is possible, starting from genes involved in the biosynthesis of pristinamycins and isolated from the strain SP92 as described in the preceding examples, to demonstrate homologous genes by hybridization of the total DNAs of strains producing streptogramins.

The DNA fragments used as a probe were:

20     The 3.9-kb XhoI-XhoI fragment isolated from pVRC1106 described in Example 6.5, the restriction map of which is presented in Figure 18. This fragment contains a portion of the gene coding for pristinamycin I synthase II.

25     The 6-kb BamHI-BamHI fragment isolated from plasmid pXL2045 described in Example 6.3, the map of which is presented in Figure 16. This fragment contains the structural genes for the two subunits of PIIA

synthase.

The total DNAs of the four strains producing streptogramins, the strain S. hygroscopicus and also the strain SP92, were digested with the restriction enzymes BamHI and XhoI. The DNA fragments thereby obtained were separated on 0.7 % agarose gel and the DNA was transferred onto a nylon membrane as described by Maniatis et al. (1989). Labelling of the 3.6-kb XhoI-XhoI and 6-kb BamHI-BamHI fragments was carried out by labelling by random priming as described in Example 9.1.2. Hybridization of the membranes was carried out in the presence of formamide at 42°C as described in Maniatis et al. (1989). Washing of the membranes after hybridization was carried out at 50 and 60°C in a solution containing SSC (Maniatis et al. (1989) diluted 10-fold and 0.1 % SDS.

The following results are demonstrated by these hybridizations:

The strain S. hygroscopicus does not display and hybridization with the two probes used.

The total DNAs (digested with XhoI and BamHI) of the strains S. ostreogirseus, S. olivaceus, S. loidensis and S. virginiae all display hybridization signals of intensity comparable to those observed on the total DNA of the strain SP92 with both probes used.

The total DNA (digested with XhoI and BamHI) of the strain S. virginiae displays signals with both probes used, but their intensity is weaker than that

observed in SP92.

This example shows that different strains of Streptomyces producing streptogramins contain genes that hybridize with genes isolated in

5 S. pristinaespiralis SP92 and which are involved in the biosynthesis of streptogramins, as presented in the preceding examples. These hybridizations thus demonstrate the homology existing between the genes involved in the biosynthesis of streptogramins of the  
10 strains SP92 and those involved in the biosynthesis of streptogramins of other strains producing streptogramins.

This example hence shows that it is possible, starting from genes isolated from SP92 and involved in  
15 the biosynthesis of streptogramins, to isolate by hybridization and cloning the homologous genes present in other strains producing streptogramins.

EXAMPLE 13: Study of the physical binding of the different S. pristinaespiralis SP 92 genes involved in the biosynthesis of pristinamycins I and pristinamycins II

5           This example illustrates how it is possible to study the physical binding of the S. pristinaespiralis SP 92 genes involved in the biosynthesis of pristinamycins I and II. This study was carried out for the purpose of showing that all these  
10 genes are grouped together on the chromosome in a cluster, and that it is hence possible by chromosome walking from the genes already identified to isolate other genes involved in the biosynthesis of pristinamycins I and II. Such an approach may be  
15 envisaged for the genes involved in the biosynthesis of other streptogramins.

#### 13.1 Restriction enzymes used for pulsed-field electrophoresis

20           The S. pristinaespiralis SP92 genome is composed of 70 % to 75 % of nucleotides containing the basis G and C. To cut its genome into a small number of large fragments, we used enzymes which recognize a sequence-rich in AT, such as AseI (AT/TAAT) and SspI (AAT/ATT) but also HindIII (A/AGCTT), EcoRI (G/AATTC),  
25 NdeI (CA/TATG) and ClaI (AT/CGAT).

#### 13.2. S. pristinaespiralis strains used for pulsed-field electrophoresis

We used the chromosomal DNA of several

strains to study by pulsed-field electrophoresis the physical binding of the genes involved in the biosynthesis of pristinamycins I and pristinamycins II. We prepared inserts as described in Example 4.1 of the chromosomal DNA of S. pristinaespiralis strain SP92, and also of the chromosomal DNA of the strains derived from SP92 whose construction is described in Examples 9.1 and 9.4. These are the strain SP92::pVRC505 in which the snaA gene has been disrupted by integration of plasmid pVRC505 (Example 9.1), and the strain SP92::pVRC404 in which the snbA gene has been disrupted by integration of plasmid pVRC404 (Example 9.4). The latter two strains were included in this study since they enabled the snaA and snbB genes to be positioned accurately on the chromosome map by exploiting the presence of sites which rarely cut chromosomal DNA, AseI, SspI, HindIII, EcoRI, NdeI and ClaI, in plasmids pVRC505 and pVRC404.

### 13.3. DNA probes used for hybridization of the fragments isolated by pulsed-field electrophoresis

We used different DNA fragments to obtain radioactively labelled probes as is described in Example 9.1, which we hybridized with the fragments separated by pulsed-field electrophoresis after enzymatic cleavage of the chromosomal DNA inserts of the three strains presented above. The probes are as follows: the 3,2-kb EcoRI-BamHI fragment isolated from plasmid pVRC701 carrying the snaB and samS genes (see

Example 9.2), the 1.5-kb BamH1-SstI fragment isolated from plasmid pVRC1000 carrying a portion of the snaD gene (see Example 6.8), the 1.1-kb XhoI-HindIII fragment isolated from plasmid pVRC402 carrying the snbA gene (see Example 6.1), the 2.4-kb PstI-PstI fragment isolated from plasmid pVRC900 carrying papA gene (see Example 6.7) and the 1.5-kb XhoI-PstI fragment isolated from plasmid pVRC509 carrying the snaC gene (see Example 6.9).

#### 13.4. Localization on the chromosome of the different genes involved in the biosynthesis of pristinaamycins I and II and study of their physical binding

Hybridization of the chromosomal DNAs of S. pristinaespiralis strains SP92, SP92::pVRC404 and SP92::pVRC505, cut by single digestions and double digestions using the six enzymes mentioned above, with the different probes described above lead to the general map shown in Figure 32: the position of major sites has been indicated, together with the position and direction of transcription of the genes involved in the biosynthesis of pristinaamycins PI and PII. Thus, it is possible to calculate the distance separating the 3 chromosomal regions containing the genes identified, namely that of the snbA, snbR, papA and papM genes (cosmid pIBV2, Example 5.2), that of the snaA, snaB, samS, snaD, snbC, snbD and snbE genes (cosmids pIBV1 and 3, Example 5.1) and lastly that of the snaC gene

(cosmid pIBV4, Example 5.6). For example, the distance between the snaA and snbA genes has been evaluated at approximately 160-170 kb. This shows that the genes already identified are all contained in a region  
5 covering only 200 kb of the chromosome of the S. pristinaespiralis strain, equivalent to less than 3 % of the total length of the genome, which we have been able to estimate at 7500 kb by the pulsed-field electrophoresis technique.

10                These results show that the genes involved in the biosynthesis of pristinamycins I and II are grouped together on the chromosome in a cluster, and that it is hence possible by chromosome walking from the genes already identified to isolate other genes involved in  
15 the biosynthesis of pristinamycins I and pristinamycins II. More generally, it is possible, by chromosome walking from any gene involved in the biosynthesis of streptogramins, to identify the other genes involved in this biosynthesis.

TABLE 1

MICROORGANISMS	ANTIBIOTICS
<b>FUNGI</b>	
<u>Micromonospora</u> sp.	Vernamycins
<b>STREPTOMYCES</b>	
<u>S. albiorectus</u>	Virginiamycins

SEQUENCE LISTING

## (1) GENERAL INFORMATION:

## (i) APPLICANT

- (A) NAME: RHONE-POULENC RORER S.A.  
(B) STREET: 20, avenue Raymond ARON  
(C) CITY: ANTONY  
(E) COUNTRY: FRANCE  
(F) POST CODE: 92165

(ii) TITLE OF INVENTION: POLYPEPTIDES INVOLVED IN  
THE BIOSYNTHESIS OF STREPTOGRAMINS, NUCLEOTIDE  
SEQUENCES CODING FOR THESE POLYPEPTIDES AND USES.

(iii) NUMBER OF SEQUENCES: 16

## (iv) COMPUTER READABLE FORM:

- (A) MEDIUM TYPE: Tape  
(B) COMPUTER: IBM PC compatible  
(C) OPERATING SYSTEM: PC-DOS/MS-DOS  
(D) SOFTWARE: PatentIn Release #1.0,  
Version #1.25 (EPO)

## (2) INFORMATION FOR SEQ ID NO: 1:

## (i) SEQUENCE CHARACTERISTICS

- (A) LENGTH: 5392 base pairs  
(B) TYPE: nucleic acid

(C) STRANDEDNESS: double

(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(iii) HYPOTHETICAL: NO

5 (iii) ANTI-SENSE: NO

(vi) ORIGINAL SOURCE

(A) ORGANISM: Streptomyces  
pristinaespiralis

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 1:
